University of Oslo

May 21, 2019

# Abstract

Abstract should be written here

# Acknowledgements

First of all I would like to thank Christine for cooking delicious food and feeding me when I need it the most. She and her food have maintained my motivation in the best way, and they are the main reason why I've survived those two years of masters.

Secondly, my annoying cohabitants have forced me to spend more time at university. I'm so glad you behave the way you do, if you were more cozy I would certainly spend more time at home and this thesis would not be the same.

Acknowledgements should be written here

-One of my mottos used to be that everything has a reason, which I used to point out whenever people were talking about things that apparently could not be described immediately. It was first when I learned about quantum mechanics that I understood I was wrong, and that is one of the reasons why quantum mechanics caught me so hardly.

# Chapter 1

## Introduction

Properties and behavior of quantum many-body systems are determined by the laws of quantum physics which have been known since the 1930s. The time-dependent Schrödinger equation describes the bounding energy of atoms and molecules, as well as the interaction between particles in a gas. In addition, it has been used to determine the energy of artificial structures like quantum dots, nanowires and ultracold condensates. [Electronic Structure Quantum Monte Carlo Michal Bajdich, Lubos Mitas]

Even though we know the laws of quantum mechanics, many challenges are encountered when calculating real-world problems. First, interesting systems often involve large number of particles, which causes expensive calculations. Second, we do not have a good model for the three-body interaction, which is vital when it comes to strong correlations. Paul Dirac recognized those problems already in 1929,

*”The general theory of quantum mechanics is now almost complete... ...The underlying physical laws necessary for the mathematical theory of a large part of physics and the whole of chemistry are thus completely known, and the difficulty is only that the exact application of these laws leads to equations much too complicated to be soluble.”*

-Paul Dirac, Quantum Mechanics of Many-Electron Systems, 1929

”At the same time, advent of computer technology has offered us a new window of opportunity for studies of quantum (and many other) problems. It spawned a “third way” of doing science which is based on simulations, in contrast to analytical approaches and experiments. In a broad sense, by simulations we mean computational models of reality based on fundamental physical laws. Such models have value when they enable to make predictions or to provide new information which is otherwise impossible or too costly to obtain otherwise. In this respect, QMC methods represent an illustration and an example of what is the potential of such methodologies.” [Electronic Structure Quantum Monte Carlo Michal Bajdich, Lubos Mitas]

History of QMC before and after the invention of electronic computers. Enrico Fermi 1930s similarities between imaginary time Schrödinger equation and stochastic processes in statistical mechanics. Metropolis VMC early 1950s. Kalos Greens’s function Monte Carlo late 1950s. Ceperly and Alder 1980 homogeneous electron gas.

Multi scale calculations are... A field of interest is how a systems behave when the interaction gets weaker. One way to model this, is to have a harmonic oscillator with a decreasing system frequency.

With machine learning, a function can be fitted to everything as long as we can define a cost function to minimize. The purpose of this thesis is to construct optimal wave functions for different systems by using machine learning.

- Low frequency (weakly interacting electrons) field of interest - Multi scale calculations
- Cartesian - Introduce the wavefunction - Mention the uncertainty principle and also quantum entanglement to catch the readers interest

## 1.1 Many-Body problem

Not possible to solve analytically

## 1.2 Machine learning

Branch of artificial intelligence

## 1.3 Goals and milestones

- Investigate a new method to solve the Many-Body problem

Figure 2.1: The first photograph of a Hydrogen atom was captured by an ultra sensitive camera in 2013. One can actually see the probability distribution  $|\Psi(\mathbf{r})|^2$  with the naked eye. Published in Phys. rev. lett. 110, 213001 (2013), *Hydrogen atoms under magnification*. [16]

Around 1900, some physicists thought that there were nothing new to be discovered in physics and all that remained was more precise measurements, as Lord Kelvin famously pointed out. [13] He could not have been more wrong. In the following years, things were observed that could only be described by a quantized theory, led by Albert Einstein's explanation of the photoelectric effect in 1905.

Immense efforts were placed on completing the theory, and contributions from an array of scientists over a period of 20 years were necessary to get it finished. In 1929, Paul Dirac stated something similar to what Lord Kelvin said 30 years earlier, but apparently with greater accuracy.

## 2.1 Introductory Quantum Physics

In this section we will present the fundamentals of the quantum theory, that will make up the framework of this project. The theory is based on David Griffith's incredible textbook, *Introduction to Quantum Mechanics*, where the reader is relegated for in-depth information.

Before we get started, we make a few assumptions in order to simplify our problem. Their most important ones are specified below with an explanation why they are valid.

- **Point-like particles:** First, all particles involved will be assumed to be point-like, i.e., that they lack spatial extension. This includes the nucleus in atomic systems, but it still makes sense since the distance from the nucleus to the electrons is known to be much larger than the nucleus extent.
- **Non-relativistic spacetime:** Second, we operate in the non-relativistic spacetime, which is valid as long as we do not approach the speed of light and we do not involve strong forces. Applying classical physics, we can find that the speed of the electron in a hydrogen atom is about 1% of the speed of light, and even though the electrons get higher speed in heavier atoms, we do not need to worry about it. The forces acting are the weak Coulomb forces.
- For specific systems we might make new assumptions and approximations. For instance, for atomic systems we will assume that the nucleus is at rest. Those approximations will be discussed consecutively.

### 2.1.1 The Schrödinger Equation

The Schrödinger equation is a natural starting point, which gives the energy eigen states of a system defined by a Hamiltonian  $\hat{\mathcal{H}}$  and its eigen functions,  $\Psi$ , which are the wave functions. The time-independent Schrödinger equation reads

$$\hat{\mathcal{H}}\Psi_n(\mathbf{r}) = \epsilon_n\Psi_n(\mathbf{r}) \quad (2.1)$$

where the Hamiltonian is the total energy operator. By analogy with the classical mechanics, this is given by

$$\hat{\mathcal{H}} = \hat{\mathcal{T}} + \hat{\mathcal{V}} \quad (2.2)$$

with  $\hat{\mathcal{T}}$  and  $\hat{\mathcal{V}}$  as the kinetic and potential energy operators respectively.

The kinetic energy yields  $T = p^2/2m$ , such that the kinetic energy operator can be represented as

$$\hat{\mathcal{T}} = \frac{\hat{\mathbf{p}}^2}{2m} \quad (2.3)$$

according to Ehrenfest's theorem. Further, the momentum operator is  $\hat{\mathbf{p}} = -i\hbar\nabla$ .

The potential energy can be split into an external part and an interaction part, where the latter is given by the Coulomb interaction. For two identical particles of charge  $q$ , the repulsive interaction gives the energy

$$V_I = k \frac{q^2}{r_{12}} \quad (2.4)$$

where  $r_{12}$  is the distance between the particles. The total Hamiltonian of a system of  $P$  identical particles takes the form

$$\hat{\mathcal{H}} = - \sum_i^P \frac{\hbar^2}{2m} \nabla_i^2 + \sum_i u_i + \sum_i^P \sum_{j>i}^P k \frac{q^2}{r_{ij}} \quad (2.5)$$

which is the farthest we can go without specifying the external potential  $u_i$ .  $r_{ij}$  is the relative distance between particle  $i$  and  $j$ , defined by  $r_{ij} \equiv |\mathbf{r}_i - \mathbf{r}_j|$ .

Setting up equation (2.1) with respect to the energies, we obtain an integral,

$$\epsilon_n = \frac{\int d\mathbf{r} \Psi_n^*(\mathbf{r}) \hat{\mathcal{H}} \Psi_n(\mathbf{r})}{\int d\mathbf{r} \Psi_n^*(\mathbf{r}) \Psi_n(\mathbf{r})}, \quad (2.6)$$

which not necessarily is trivial to solve. If we take the wave function squared we get the probability distribution,

$$P(\mathbf{r}) = \Psi_n^*(\mathbf{r}) \Psi_n(\mathbf{r}) = |\Psi_n(\mathbf{r})|^2 \quad (2.7)$$

so the nominator is simply the integral over all probabilities. If the wave function is normalized correctly, this should always give 1. Assuming that is the case, the expectation value can be expressed more elegantly by using Dirac notation,

$$E[\Psi] = \langle \Psi | \hat{\mathcal{H}} | \Psi \rangle, \quad (2.8)$$

where the first part,  $\langle \Psi |$  is called a bra and the last part,  $|\Psi \rangle$  is called a ket. At first this might look artificial and less informative, but it simplifies the notation significantly. More information about the notation is found in Appendix A.

In many cases we do not know the exact wave function, and need to rely on a trial wave function guess. Henceforth, we will use  $\Psi$  as the exact total wave function,  $\psi$  as the exact single particle function (SPF),  $\Psi_T$  as the total trial wave function and  $\phi$  as the trial SPF. [9]

### 2.1.2 The Variational Principle

In the equations above, the presented wave functions are assumed to be the exact eigen functions of the Hamiltonian. But often we do not know the exact wave functions, and we need to guess what the wave functions might be. In those cases we make use of the variational principle, which states that only the exact ground state wave function is able to give the ground state energy. All other wave functions that fulfill the required properties (see section 2.2) give higher energies, and mathematically we can express the statement

$$\epsilon_0 \leq \langle \Psi_T | \hat{\mathcal{H}} | \Psi_T \rangle. \quad (2.9)$$

Variational Monte-Carlo is a method based on (and named after) the variational principle, where we vary the trial wave function in order to obtain the lowest energy. It will be detailed in chapter (4).

### 2.1.3 Postulates of Quantum Mechanics

The quantum theory is built on a few fundamental postulates, which will always be true. Before we go further, we will take a quick look at some of them.

1. Associated with any particle moving in a conservative field of force is a wave function which determines everything that can be known about the system.
2. With every physical observable  $q$  there is associated an operator  $Q$ , which when operating upon the wave function associated with a definite value of that observable will yield that value times the wave function.
3. Any operator  $Q$  associated with a physically measurable property  $q$  will be Hermitian.
4. The set of eigen functions of operator  $Q$  will form a complete set of linearly independent functions.
5. For a system described by a given wave function, the expectation value of any property  $q$  can be found by performing the expectation value integral with respect to that wave function.
6. The time evolution of the wave function is given by the time-dependent Schrodinger equation.

## 2.2 The Trial Wave Function

By the first postulate of quantum mechanics, the wave function contains all the information specifying the state of the system. This means that all observable in classical mechanics can also be measured from the wave function, which makes finding the wave function our main goal.

The trial wave function needs to meet some requirements in order to be used in the variational principle, and we thus need to make an educated guess on the wave function where the requirements are fulfilled. The requirements are the following:

1. **Normalizability:** The wave function needs to be normalizable to make physical sense. The total probability should always be 1, and a wave function that cannot be normalized will not have a finite total probability. The consequence is that the wave function needs to converge to zero when the positions get large.
2. **Cusp condition:** The cusp condition (also called the Kato theorem) states that the wave function should have a cusp where the potential explodes. An example on this is when charged particles come close to each other.
3. **Symmetry and anti-symmetry:** The wave function needs to be either symmetric or anti-symmetric under exchange of two coordinates, dependent on whether the particles are fermions or bosons. More about this in the next section.

### 2.2.1 Bosons and fermions

Assume that we have a permutation operator  $\hat{P}$  which exchanges two coordinates in the wave function,

$$\hat{P}(i \rightarrow j)\Psi_n(\mathbf{x}_1, \dots, \mathbf{x}_i, \dots, \mathbf{x}_j, \dots, \mathbf{x}_M) = p\Psi_n(\mathbf{x}_1, \dots, \mathbf{x}_j, \dots, \mathbf{x}_i, \dots, \mathbf{x}_M), \quad (2.10)$$

where  $p$  is just a factor which comes from the transformation. If we again apply the  $\hat{P}$  operator, we should switch the same coordinates back, and we expect to end up with the initial wave function. For that reason,  $p = \pm 1$ .<sup>1</sup>

The particles that have an antisymmetric (AS) wavefunction under exchange of two coordinates are called fermions, named after Enrico Fermi, and have half integer spin. On the other hand, the particles that have a symmetric (S) wavefunction under exchange of two coordinates are called bosons, named after Satyendra Nath Bose, and have integer spin.

It turns out that because of their antisymmetric wavefunction, two identical fermions cannot be found at the same position at the same time, known as the Pauli principle. This causes some difficulties when dealing with multiple fermions, because we always need to ensure that the total wavefunction becomes zero if two identical particles happen to be at the same position. To do this, we introduce a Slater determinant as described below. In this particular project, we are going to focus on electrons and therefore fermions. However, much of the theory applies for bosons as well.

### 2.2.2 Slater determinant

For a system of more particles we can define a total wavefunction, which is a composition of all the single particle wavefunctions (SPF) and contains all the information about the system. For fermions we need to compile the SPFs such that the Pauli principle is fulfilled at all times. One way to do this is by setting up the SPFs in a determinant, known as a Slater determinant.

Consider a system of two identical fermions with SPFs  $\phi_1$  and  $\phi_2$  at positions  $\mathbf{r}_1$  and  $\mathbf{r}_2$  respectively. The way we define the wavefunction of the system is then

$$\Psi_T(\mathbf{r}_1, \mathbf{r}_2) = \begin{vmatrix} \phi_1(\mathbf{r}_1) & \phi_2(\mathbf{r}_1) \\ \phi_1(\mathbf{r}_2) & \phi_2(\mathbf{r}_2) \end{vmatrix} = \phi_1(\mathbf{r}_1)\phi_2(\mathbf{r}_2) - \phi_2(\mathbf{r}_1)\phi_1(\mathbf{r}_2), \quad (2.11)$$

which is set to zero if the particles are at the same position. The determinant yields the same no matter how big the system is.

The Slater determinant is just an ansatz since it does not come from any analytical calculations, and we therefore need to denote it as the trial wave function. Additionally, the Slater determinant above contains the radial part only, because the single particle functions are the radial part by convention. For a general Slater determinant, the spin part needs to be included as well, giving

$$\Psi(\mathbf{r}_1, \mathbf{r}_2, \dots, \mathbf{r}_N) = \begin{vmatrix} \psi_1(\mathbf{r}_1) & \psi_2(\mathbf{r}_1) & \dots & \psi_N(\mathbf{r}_1) \\ \psi_1(\mathbf{r}_2) & \psi_2(\mathbf{r}_2) & \dots & \psi_N(\mathbf{r}_2) \\ \vdots & \vdots & \ddots & \vdots \\ \psi_1(\mathbf{r}_N) & \psi_2(\mathbf{r}_N) & \dots & \psi_N(\mathbf{r}_N) \end{vmatrix} \quad (2.12)$$

where the  $\psi$ 's are the true single particle wave functions, which are the tensor products

$$\psi = \phi \otimes \xi \quad (2.13)$$

with  $\xi$  as the spin part. How the spin can be factorized out for electronic systems will be shown below.

Similar to the Slater determinant, a Slater permanent might be included for bosonic systems. The permanent of a matrix is similar to the determinant, but all negative signs are replaced by positive signs.

---

<sup>1</sup>Actually, in two-dimensional systems we have a third possibility which gives an *anyon*. The theory on this was developed by J.M. Leinaas and J. Myrheim during the 1970's. [5]

### 2.2.3 Simplification of Slater determinant for electronic systems

For our purpose we will study fermions of spin  $\sigma = \pm 1/2$  only, i.e., electrons and protons. In this particular case, the SPFs can be arranged in spin-up and spin-down parts, such that the Slater determinant can be simplified to

$$\Psi(\mathbf{r}_1, \mathbf{r}_2, \dots, \mathbf{r}_N) = \begin{vmatrix} \phi_1(\mathbf{r}_1)\xi_\uparrow & \phi_1(\mathbf{r}_1)\xi_\downarrow & \dots & \phi_{N/2}(\mathbf{r}_1)\xi_\uparrow & \phi_{N/2}(\mathbf{r}_1)\xi_\downarrow \\ \phi_1(\mathbf{r}_2)\xi_\uparrow & \phi_1(\mathbf{r}_2)\xi_\downarrow & \dots & \phi_{N/2}(\mathbf{r}_2)\xi_\uparrow & \phi_{N/2}(\mathbf{r}_2)\xi_\downarrow \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ \phi_1(\mathbf{r}_{N-1})\xi_\uparrow & \phi_1(\mathbf{r}_{N-1})\xi_\downarrow & \dots & \phi_{N/2}(\mathbf{r}_{N-1})\xi_\uparrow & \phi_{N/2}(\mathbf{r}_{N-1})\xi_\downarrow \\ \phi_1(\mathbf{r}_N)\xi_\uparrow & \phi_1(\mathbf{r}_N)\xi_\downarrow & \dots & \phi_{N/2}(\mathbf{r}_N)\xi_\uparrow & \phi_{N/2}(\mathbf{r}_N)\xi_\downarrow \end{vmatrix}.$$

Here we assume that two particles of opposite spin are found at the same position, which makes the number of fermions with spin up equal to the number of fermions with spin down. This is obviously not a assumption that always will hold, but it eases the calculations.

Now recall that all particles with odd position indices ( $\mathbf{r}_1, \mathbf{r}_3, \dots$ ) have spin up, such that  $\phi_j(\mathbf{r}_i)\xi_\downarrow = 0$  where  $j = 1, \dots, N/2$  and  $i$  spans over all the odd positions indices. The same applies for particles with even position indices and spin down, and we get

$$\Psi(\mathbf{r}_1, \mathbf{r}_2, \dots, \mathbf{r}_N) = \begin{vmatrix} \phi_1(\mathbf{r}_1)\xi_\uparrow & 0 & \dots & \phi_{N/2}(\mathbf{r}_1)\xi_\uparrow & 0 \\ 0 & \phi_1(\mathbf{r}_2)\xi_\downarrow & \dots & 0 & \phi_{N/2}(\mathbf{r}_2)\xi_\downarrow \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ \phi_1(\mathbf{r}_{N-1})\xi_\uparrow & 0 & \dots & \phi_{N/2}(\mathbf{r}_{N-1})\xi_\uparrow & 0 \\ 0 & \phi_1(\mathbf{r}_N)\xi_\downarrow & \dots & 0 & \phi_{N/2}(\mathbf{r}_N)\xi_\downarrow \end{vmatrix},$$

which by row operations can be found to be row equivalent with

$$\Psi(\mathbf{r}_1, \mathbf{r}_2, \dots, \mathbf{r}_N) = \begin{vmatrix} \phi_1(\mathbf{r}_1)\xi_\uparrow & \phi_2(\mathbf{r}_1)\xi_\uparrow & \dots & 0 & 0 \\ \phi_1(\mathbf{r}_3)\xi_\uparrow & \phi_2(\mathbf{r}_3)\xi_\uparrow & \dots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & \phi_{N/2-1}(\mathbf{r}_{N-2})\xi_\downarrow & \phi_{N/2}(\mathbf{r}_{N-2})\xi_\downarrow \\ 0 & 0 & \dots & \phi_{N/2-1}(\mathbf{r}_N)\xi_\downarrow & \phi_{N/2}(\mathbf{r}_N)\xi_\downarrow \end{vmatrix}.$$

This means that we can split the Slater determinant in a spin up part and a spin down part,

$$\Psi(\mathbf{r}_1, \mathbf{r}_2, \dots, \mathbf{r}_N) = |\hat{D}_\uparrow| \cdot |\hat{D}_\downarrow| \quad (2.14)$$

which saves us from a lot of computations. For a detailed explanation of the splitting, appendix I of Daniel Nissenbaum's dissertation is an excellent read. [14] Szabo & Ostlund in [8] is also a good explanation.

### 2.2.4 Basis set

To go further, we need to define a basis set,  $\phi_n(\mathbf{r})$  which should be chosen carefully based on the system. For a few systems, we know the exact basis of the non-interacting case, and it is thus a natural basis to use in the Slater determinant. For other systems, the choice of basis might depend on the situation, where we typically need to weigh computational time against accuracy. Concrete examples on both cases will be presented in chapter (3).

Often, one will see that the basis is optimized by the Hartree-Fock method. Using this basis in a single Slater determinant, we obtain the Hartree-Fock energy which sometimes

is quite accurate. To get an even better energy estimate, we need to add more Slater determinants, which is the task of the post Hartree-Fock methods. More about this in chapter (4-6).

### 2.2.5 Jastrow factor

From electrostatics we know that identical, charged particles will repel each other. This means that the probability of finding two particles close to each other should be low, which needs to be baked into the wave function. One way to do this is to simply multiply the wave function with the distance between the particles; the smaller distance the lower probability. Nevertheless, this does not fulfill the normalizability requirement of the trial wave function, but the same idea lies behind the Padé-Jastrow factor, which reads

$$J(\mathbf{r}; \beta, \gamma) = \exp \left( \sum_{i=1}^P \sum_{j>i}^P \frac{a_{ij} r_{ij}}{1 + \beta r_{ij}} \right). \quad (2.15)$$

where  $r_{ij}$  again is the relative distance between particle  $i$  and  $j$ ,  $\beta$  is a variational parameter, while  $a_{ij}$  depends on the spin of the interacting objects in the following way:

$$a_{ij} = \begin{cases} e^2/(d+1) & \text{if } i, j \text{ are particles of same spin} \\ e^2/(d-1) & \text{if } i, j \text{ are particles of opposite spin,} \end{cases} \quad (2.16)$$

for dimensions  $d \in [2, 3]$  where  $e$  is the elementary charge. We will later use natural and atomic units, and set  $e = 1$ , which for two dimensions gives  $a_{ij} = 1/3$  (same spin) or  $a_{ij} = 1$  (opposite spin) and for three dimensions  $a_{ij} = 1/4$  (same spin) and  $a_{ij} = 1/2$  (opposite spin).

This Jastrow factor is known to give accurate results for fermions and bosons because it gives the correct cusp condition, and it is the one we gonna use in the standard variational Monte-Carlo simulations.

## 2.3 Electron density

In quantum many-body computations, the electron density is frequently calculated, and there are several reasons for this. Firstly, the electron density can be found experimentally, such that the calculations can be benchmarked. Secondly, the electron density is very informative, since information about all particles can be gathered in one plot.

The  $N$ -body electron density can be found by integrating over all particles but  $N$ ,

$$\rho_i(\mathbf{r}) = \int_{-\infty}^{\infty} d\mathbf{r}_1 \dots d\mathbf{r}_{i-1} d\mathbf{r}_{i+N} \dots d\mathbf{r}_P |\Psi(\mathbf{r}_1, \dots, \mathbf{r}_P)|^2. \quad (2.17)$$

where  $P > N$ .

### 2.3.1 One-body density

The one-body density is the most applied electron density, and is sometimes referred to as the electron density. For the two particle case, the one-body density gives the probability of finding one particle at a relative distance  $r$  to the other. For more particles, the one-body density gives the probability of finding the mass center of the remaining particles at a relative distance  $r$  from one of the particles.

Numerically, the one-body density is found by dividing the space into bins of equal sizes at different radii and counting the number of particles in each bin throughout the sampling.

Figure 2.2: One can find the onebody density by dividing the volume around a particle with coordinates  $\vec{r}_i$  into bins and then count the number of particles, here illustrated in two dimensions.

### 2.3.2 Two-body density

For the one-body density, we integrate over all the particles but one, which corresponds to counting number of particles in each bin. For the two-body density, the integrate over all particles but a *particle pair*, which means that we numerically need to find the position of each particle pair.

# Chapter 3

## Systems

We must be clear that when it comes to atoms, language can be used only as in poetry.

---

Niels Bohr, [4]

Figure 3.1: The quantum harmonic oscillator, with the Hermite functions represented up to 4th order. As in classical mechanics, the harmonic oscillator can describe various quantum systems, such as lattice vibration (phonons) and quantum fields.

When defining a system, we also need to specify the basis set to be used. The single particle functions are often known, and they are well-suited as a basis for the total

### 3.1 Quantum dots

Quantum dots are very small particles, and contain fermions or bosons hold together by an external potential. Since these particles have discrete electronic states like an atom, they are often called artificial atoms.

In this thesis we will, among other systems, study electrons trapped in harmonic oscillators, where the external potential affecting particle  $i$  is given by

$$u_i = \frac{1}{2}m\omega^2 r_i^2. \quad (3.1)$$

where  $m$  is the mass of particle  $i$ ,  $\omega$  is the oscillator frequency and  $r_i$  is the relative distance from particle  $i$  to the center of the trap.

Using natural units as described in Appendix B, we can write the Hamiltonian as

$$\hat{\mathcal{H}} = \sum_{i=1}^P \left( -\frac{1}{2}\nabla_i^2 + \frac{1}{2}\omega^2 r_i^2 \right) + \sum_{i<j} \frac{1}{r_{ij}} \quad (3.2)$$

where the energy is scaled with respect to atomic units and lengths are scaled with respect to the Bohr radius.

The exact solutions of the non-interacting Hamiltonian are the Hermite functions,

$$\phi_n(x) = H_n(\sqrt{\omega}x) \exp(-\omega x^2/2) \quad (3.3)$$

which can be used as the basis.  $H_n(x)$  is the Hermite polynomial of  $n$ 'th degree, and the first four Hermite functions are illustrated in figure (3.1). The energy of a particle at energy level  $n$  in a  $D$  dimensional harmonic oscillator is given by

$$E_n = \omega \left( n + \frac{D}{2} \right). \quad (3.4)$$

We will study closed-shell systems only, since the Slater determinant in that case is unambiguous. For open shells, the total Slater determinant is a linear combination of all the possible Slater determinants. The number of particles of closed-shell systems are called magic numbers, which in two dimensions are  $N = 2, 6, 12, \dots$ . In general, the magic numbers are given by

$$N = s \binom{n+D}{D} \quad (3.5)$$

where  $s$  is the number of spin configurations (2),  $n$  is the principal quantum number and  $d$  is the number of dimensions. This is a direct consequence of the Pauli principle, where we in the ground state can have two particles with radial wave functions  $\Phi_{n_x=0, n_y=0}$ , in the next energy level we have have 4 particles with radial wave functions  $\Phi_{n_x=1, n_y=0}$  and  $\psi_{n_x=0, n_y=1}$  with degeneracy 2 and so on.

Figure 3.2: Possible states of a two dimensional harmonic oscillator.

Figure 3.3: Possible states of a three dimensional harmonic oscillator.

## 3.2 Atomic systems

We will also investigate real atoms, where we freeze out the nucleonic degrees of freedom known as the Born-Oppenheimer approximation. The electrons will in fact affect the nucleus, but due to the mass difference this effect will be negligible.

We again have Coulomb interaction between the electrons and the nucleus, and since we assume the latter to be at rest at the origin, the external potential affecting particle  $i$

is

$$u_i = -\frac{1}{2}k\frac{Ze^2}{r_i}, \quad (3.6)$$

where  $Z$  is the atomic number (number of protons inside the nucleus). The total Hamiltonian is given in (Hartree) atomic units,

$$\hat{\mathcal{H}} = \sum_{i=1}^P \left( -\frac{1}{2}\nabla_i^2 - \frac{1}{2}\frac{Z}{r_i} + \frac{l(l+1)}{2r_i^2} \right) + \sum_{i<j} \frac{1}{r_{ij}}, \quad (3.7)$$

which also is discussed in Appendix B. For the non-interacting case, the energies are given by the Bohr formula

$$E_n = -\frac{Z^2}{2n^2}. \quad (3.8)$$

For atomic systems, it is convenient to use spherical coordinates, which allows us to split up the wave function in a radial part and an angular part,

$$\psi_{nlm}(r, \theta, \phi) = R_{nl}(r)Y_l^m(\theta, \phi) \quad (3.9)$$

The exact radial part for the non-interacting case is called the hydrogen-like orbitals, that is

$$R_{nl}(r) \propto r^l e^{-Zr/n} \left[ L_{n-l-1}^{2l+1} \left( \frac{2r}{n} Z \right) \right] \quad (3.10)$$

where  $L_q^p(x)$  are the *associated Laguerre polynomials* or *generalized Laguerre polynomials*. More about them and how to calculate them recursively can be found in Appendix C.

The angular part is given by the *spherical harmonics*

$$Y_l^m(\theta, \phi) \propto P_l^m(\cos \theta) e^{im\phi} \quad (3.11)$$

where  $P_l^m(x)$  are the *associated Legendre polynomials*. The complex part in the spherical harmonics causes some difficulties, and we will therefore instead use the solid harmonics

$$S_l^m(r, \theta, \phi) \propto r^l P_l^{|m|}(\cos \theta) \begin{cases} \cos(m\phi) & \text{if } m \geq 0 \\ \sin(|m|\phi) & \text{if } m < 0. \end{cases} \quad (3.12)$$

Again we will study closed shells only, but for atoms we will introduce subshells as well, which are dependent on the azimuthal quantum number  $l$  in addition to the principal quantum number  $n$ . In general, we have that  $l \in [0, n-1]$  such that we only have one subshell for  $n = 1$ . Traditionally, the first few subshells are denoted with  $s, p, d$  and  $f$ , and the meaning can be found in table (3.1), together with number of electrons in each subshell.

Table 3.1: Table of the first subshells

Subshell label	$l$	Max electrons	Name
$s$	0	2	sharp
$p$	1	6	principal
$d$	2	10	diffuse
$f$	3	14	fundamental
$g$	4	18	alphabetic

For Helium, we have two electrons with  $n = 1$ , which means that both have  $l = 0$  and both electrons are in the  $s$ -subshell. We can thus write the electron configuration as  $1s^2$ .

Similar as for the principal quantum number  $n$ , we can use the thumb rule the lower  $l$  the lower energy, such that for Beryllium all four electrons are still in the  $s$ -subshell. Beryllium therefore has electron configuration  $1s^2 2s^2$  or [He]  $2s^2$ . Since both subshells are fully occupied, Beryllium can be included in our closed-shell calculations.

If we continue with the same rules, we see that the next closed-shell atom has a fully occupied  $p$ -subshell as well, which is Neon with 10 electrons. This is a noble gas, and we can write the electron configuration as [Ne]  $2p^6$ . All noble gases have endings  $Xs^2 Xp^6$ , which is the reason why they always have 8 valence electrons.

We can now compare this to the periodical system, and observe that the two first rows agrees with the theory presented above: The first row has two elements and the second has eight. However, the third one also has eight elements, which does not fit our theory. The reason is that the angular momentum contribution is not taken into account, i.e., we need to include the Hamiltonian term

$$V_L = \frac{l(l+1)}{2r^2} \quad (3.13)$$

as well. If we do so, we see that the thumb rule defined above not always holds. Sometimes a low  $l$  in a higher  $n$  causes lower energy than a high  $l$  in a lower  $n$ .

”Colloquially, we call such solutions and derived properties as electronic structure.”

### 3.3 Molecular systems

For molecular systems the same principles applies as for an atom, but we now have multiple contributions to the external potential.

### 3.4 Bose-Einstein Condensation

Already in 1925, A. Einstein predicted that all bosons occupy the same quantum state for temperatures close to the absolute zero. [NEED REFERENCE, Bose–Einstein Condensation in Dilute Gases] It would take 70 years for someone to come up with an experiment to prove the prediction, when M.H. Andersen et.al. managed reach those extreme temperatures using laser cooling. [NEED REFERENCE, Observation of bose-einstein condensation in a dilute atomic vapor.]

The bosons do not interact with the Coulomb interaction as we have seen above: The actual interaction is unknown, but we can model it with a hard-sphere potential...

## Quantum Monte-Carlo Methods

Great quote.

---

Author

Figure 4.1: Caption

Some great methods are developed over the past decade. We will focus on the Hartree-Fock and variational Monte Carlo methods and give a detailed explanation of those methods. Additionally, the well-known methods configuration interaction and coupled cluster will be described briefly for some kind of completeness.

Monte Carlo methods in quantum mechanics are a bunch of methods that are built on diffusion processes, and includes Variational Monte Carlo (VMC), Diffusion Monte Carlo (DMC) and others. The common denominator is that we move particles in order to find the optimal configuration, usually where the energy is minimized. The particles can be moved isotropic, i.e., uniformly in all directions, or they can be affected by a drift force which makes the process anisotropic.

### 4.0.1 Isotropic processes

In isotropic processes, we have random walks where the particles move randomly in space which falls under the category Markov chains. If we assume constant timestep, the step index can be considered the time, thus we have a time-dependent probability density  $P(\mathbf{x}, t)$ . This probability density needs to satisfy the isotropic diffusion equation,

$$\frac{\partial P(\mathbf{x}, t)}{\partial t} = D \frac{\partial^2}{\partial \mathbf{x}^2} P(\mathbf{x}, t). \quad (4.1)$$

### 4.0.2 Anisotropic processes

For anisotropic processes, we have a drift and the moves are no longer considered random but falls still under the category Markov chains. Because of the drift, we need to rewrite the diffusion equation and we end up with the Fokker-Planck equation,

$$\frac{\partial P(\mathbf{x}, t)}{\partial t} = D \frac{\partial}{\partial \mathbf{x}} \left( \frac{\partial}{\partial \mathbf{x}} - F \right) P(\mathbf{x}, t) \quad (4.2)$$

which needs to be satisfied. The new positions in coordinate space are given as solution of the Langevin equation

$$\frac{\partial \mathbf{x}(t)}{\partial t} = D \mathbf{F}(\mathbf{x}(t)) + \eta \quad (4.3)$$

### 4.0.3 Variational Monte Carlo

The variational Monte-Carlo (hereafter, VMC) method is today widely used when it comes to the study of ground state properties of quantum mechanical systems. It is a Markov chain Monte-Carlo method which makes use of Metropolis sampling, and has been used in studies of fermionic systems since the 1970's. [18] If we go back to the variational principle in equation (2.9), we see that by choosing a wave function which satisfies the criteria, we will get an energy larger or equal to the ground state energy.

There are two main problems we need to solve

1. We seldomly know the correct wave function
2. The integral we need to find the energy is hard or impossible to solve

Let us first determine the last problem, which often is considered as the root of all evil. Solving this integral by integration cannot be done, but we can approximate it with a sum,

$$\begin{aligned} E &\leq \frac{\int \Psi_T(\mathbf{r})^* \hat{H} \Psi_T(\mathbf{r}) d\mathbf{r}}{\int \Psi_T(\mathbf{r})^* \Psi_T(\mathbf{r}) d\mathbf{r}} \\ &= \int P(\mathbf{r}) E_L(\mathbf{r}) d\mathbf{r} \\ &\approx \frac{1}{M} \sum_{i=1}^M E_L(\mathbf{r}_i) \end{aligned} \quad (4.4)$$

which is a common trick in statistical physics. The local energy is defined as

$$E_L(\mathbf{r}) \equiv \frac{1}{\Psi_T(\mathbf{r})} \hat{H} \Psi_T(\mathbf{r}) \quad (4.5)$$

and the  $\mathbf{r}_i$  is withdrawn from the probability distribution  $P(\mathbf{r})$ , which is given by

$$P(\mathbf{r}) = \frac{|\Psi_T(\mathbf{r})|^2}{\int |\Psi_T(\mathbf{r})|^2 d\mathbf{r}}. \quad (4.6)$$

The energy found from equation (4.4) is an expectation value, and we therefore know that the true energy lies within the standard error. When increasing the number of energies drawn from the distribution,  $M$ , henceforth denoted as Monte-Carlo cycles, the standard error decreases and we get a more accurate energy. In the limit when  $M$  goes to infinity, the variance should approach zero,

$$\langle E \rangle = \lim_{M \rightarrow \infty} \frac{1}{M} \sum_{i=1}^M E_L(\mathbf{r}_i). \quad (4.7)$$

For more statistical details, see [18].

So far, so good, but how about the first problem stated above? How do we find the correct wave function? In VMC, we define a wave function with variational parameters, which are adjusted in order to minimize the energy for every iteration. Of course, we need a decent initial guess, which is usually based on our physical intuition. We will later examine how much physical intuition we need to get an acceptable result.

For every iteration, we run  $M$  Monte-Carlo cycles where we withdraw a new position  $\mathbf{r}_i$ . Whether or not the proposed move should be accepted is determined by the Metropolis algorithm.

#### 4.0.3.1 The Metropolis Algorithm

Metropolis sampling is a method of accepting or rejecting moves in Markov chain, and is today widely used. The genius of the metropolis algorithm, is that the acceptance of a move is not based on the probabilities themselves, but the ratio between the new and the old probability. In that way, we avoid calculating the sum over all probabilities, which often is expensive or even impossible to calculate.

In its simplest form, the move is proposed randomly, and it is accepted if the ratio is larger than a random number between 0 and 1. We will call this approach **brute-force Metropolis sampling**. However, with this approach a lot of moves will be rejected, which results in waste CPU time. A better method is **importance sampling**, which makes an educated guess of the best way to move based on diffusion processes, and move the particle in that direction.

A time-dependent probability density needs to satisfy the Fokker-Planck equation

# Chapter 5

## Hartree-Fock

Hartree-Fock is like a good kitchen tool; it can be used to prepare several different dishes.

---

Morten Hjorth-Jensen

Figure 5.1: Caption

Hartree-Fock is an algorithm for finding an approximative expression for the ground state energy of a Hamiltonian. Ever since the childhood of many-body quantum mechanics, it has been an important quantum many-body method due to its accuracy contra expensiveness.

The method sets up a mean-field potential, often called the Hartree-Fock potential, which replaces the two-body repulsive interaction found in electronic structure calculations. Thereafter, a new basis is expanded in a given basis, and the optimal coefficients with respect to the mean-field constraint are generated. Traditionally, the method has been called the self-consistent field method, but today Hartree-Fock is mostly used.

Since we are replacing the interaction term, we need to define a new operator to replace the Hamiltonian, known as the Hartree-Fock operator,

$$\hat{h}^{\text{HF}} = \hat{t} + \hat{u}_{\text{ext}} + \hat{u}^{\text{HF}}. \quad (5.1)$$

The  $\hat{u}^{\text{HF}}$  is a single-particle potential, and will later be determined by the algorithm. The operator can be used directly in the Schrödinger equation

$$\hat{h}^{\text{HF}} |p\rangle = \epsilon_\alpha |p\rangle \quad (5.2)$$

where the obtained energy is called the Hartree-Fock energy. The Hartree-Fock basis is found from the following expansion,

$$|p\rangle = \sum_{\lambda} C_{p\lambda} |\lambda\rangle, \quad (5.3)$$

where the initial basis is denoted with Greek letters and the new basis is denoted with Roman letters.  $C_{p\lambda}$  are the coefficients that form an optimal basis.

## 5.1 Restricted Hartree-Fock

When we calculated the reference energy above, our basis contained only one Slater determinant, more specifically the ground state. In Hartree-Fock, we still have a single Slater determinant basis, but we now construct new SPFs with the constraint of minimizing the energy.

In general, one can change from one single-particle basis to another by a unitary transform,

$$|p\rangle = \sum_{\alpha} c_{p\alpha} |\alpha\rangle, \quad (5.4)$$

where we use greek letters for the old basis and roman letters for the new one. If we then insert into (??), we get a find energy formula with coefficients,  $C_{p\lambda}$ , that we can vary

$$E = \sum_p \sum_{\alpha\beta} C_{p\alpha}^* C_{p\beta} \langle \alpha | \hat{h}_0 | \beta \rangle + \frac{1}{2} \sum_{pq} \sum_{\alpha\beta\gamma\delta} C_{p\alpha}^* C_{q\beta}^* C_{p\gamma} C_{q\delta} \langle \alpha\beta | \hat{v} | \gamma\delta \rangle_{\text{AS}}. \quad (5.5)$$

Further, we assume that also our new basis is orthonormal, i.e.,

$$\langle p | q \rangle = \sum_{\alpha} c_{p\alpha}^* c_{q\alpha} \langle \alpha | \alpha \rangle = \sum_{\alpha} c_{p\alpha}^* c_{q\alpha} = \delta_{pq} \quad (5.6)$$

$$\Rightarrow \sum_{\alpha} c_{p\alpha}^* c_{q\alpha} - \delta_{pq} = 0 \quad (5.7)$$

We now have a function,  $E$ , that we want to minimize with respect to a constraint given in equation (5.7). This is a typical situation where Lagrange Multipliers is convenient to use, which in this case can be written as

$$\mathcal{L}(\{C_{p\alpha}\}) = E(\{C_{p\alpha}\}) - \sum_a \varepsilon_a \left( \sum_{\alpha} c_{p\alpha}^* c_{q\alpha} - \delta_{pq} \right). \quad (5.8)$$

The variation in reference energy is then find to be

$$\delta E = \sum_{k\alpha} \frac{\partial E}{\partial C_{k\alpha}^*} \delta C_{k\alpha}^* + \sum_{k\alpha} \frac{\partial E}{\partial C_{k\alpha}} \delta C_{k\alpha} - \sum_{k\alpha} \varepsilon_k (C_{k\alpha} \delta C_{k\alpha}^* + C_{k\alpha}^* \delta C_{k\alpha}) \quad (5.9)$$

which is zero when  $E$  is minimized. Each coefficient  $C_{k\alpha}$  and  $C_{k\alpha}^*$  is independent, so they can be varied independently. Thus

$$\left( \frac{\partial E}{\partial C_{k\alpha}^*} - \varepsilon_k C_{k\alpha} \right) \delta C_{k\alpha}^* = 0, \quad (5.10)$$

which is satisfied if and only if

$$\frac{\partial E}{\partial C_{k\alpha}^*} - \varepsilon_k C_{k\alpha} = 0 \quad \forall k, \alpha \quad (5.11)$$

The first term can be derived from (5.9), and reads

$$\frac{\partial E}{\partial C_{k\alpha}^*} = \sum_{\beta} C_{k\beta} \langle \alpha | \hat{h}_0 | \beta \rangle + \sum_p^N \sum_{\beta\gamma\delta} C_{p\beta}^* C_{k\gamma} C_{p\delta} \langle \alpha\beta | \hat{v} | \gamma\delta \rangle_{\text{AS}}. \quad (5.12)$$

This results in the equation

$$\sum_{\gamma} \hat{h}_{\alpha\gamma}^{\text{HF}} C_{k\gamma} = \varepsilon_k C_{k\alpha} \quad (5.13)$$

where we have defined

$$\hat{h}_{\alpha\gamma}^{\text{HF}} \equiv \langle \alpha | \hat{h}_0 | \gamma \rangle + \sum_p^N \sum_{\beta\delta} C_{p\beta}^* C_{p\delta} \langle \alpha\beta | \hat{v} | \gamma\delta \rangle_{\text{AS}}. \quad (5.14)$$

We recognize that (5.13) can be written as a matrix-vector product

$$\hat{h}^{\text{HF}} C_k = \varepsilon_k^{\text{HF}} C_k \quad (5.15)$$

where  $C_k$  are columns in our coefficient matrix and  $\varepsilon_k^{\text{HF}}$  are just the eigenvalues of  $\hat{h}^{\text{HF}}$ , they have no physical significance. We will use this equation to find the optimal SPFs (optimal  $C_k$ 's) and then find the energy from equation (5.9).

$$\hat{h}^{\text{HF}}(C_k^{i+1}) C_k^i = \varepsilon_k^{\text{HF}} C_k^i \quad (5.16)$$

Usually one initialize this with  $\hat{C} = \hat{\mathcal{I}}$ , the identity matrix.

## 5.2 Unrestricted Hartree-Fock

# Chapter 6

## Post Hartree-Fock Methods

Great quote.

---

Author

Figure 6.1: Caption

Post Hartree-Fock methods are usually *ab initio* methods where Hartree-Fock can be used as input. The term *ab initio* means from first principles, implying that only physical constants are put into the methods. The Monte-Carlo methods are not considered *ab initio* as nonphysical hyper parameters are required. The methods we will discuss here are the **configuration interaction** method and the **coupled cluster** method.

## 6.1 Configuration Interaction

The configuration interaction method is in many ways the the most intuitive method, and some will argue that it is the natural starting point.

Often, we know the true wavefunctions  $|\Phi_i\rangle$  in the external potential, but are off when interaction is added

$$\hat{H}_0 |\Phi_i\rangle = \varepsilon_i |\Phi_i\rangle, \quad (\hat{H}_0 + \hat{H}_I) |\Phi_i\rangle \neq \varepsilon_i |\Phi_i\rangle. \quad (6.1)$$

However, the Slater determinants form a ket basis, meaning we can write out eigenstates of  $\hat{H}_I$  as a linear combination of the determinants

$$\begin{aligned} |\Psi_0\rangle &= C_0^{(0)} |\Phi_0\rangle + C_1^{(0)} |\Phi_1\rangle + \dots + C_{N-1}^{(0)} |\Phi_{N-1}\rangle \\ |\Psi_1\rangle &= C_0^{(1)} |\Phi_0\rangle + C_1^{(1)} |\Phi_1\rangle + \dots + C_{N-1}^{(1)} |\Phi_{N-1}\rangle \\ |\Psi_2\rangle &= C_0^{(2)} |\Phi_0\rangle + C_1^{(2)} |\Phi_1\rangle + \dots + C_{N-1}^{(2)} |\Phi_{N-1}\rangle \\ &\vdots \\ |\Psi_{N-1}\rangle &= C_0^{(N-1)} |\Phi_0\rangle + C_1^{(N-1)} |\Phi_1\rangle + \dots + C_N^{(N-1)} |\Phi_{N-1}\rangle \end{aligned} \quad (6.2)$$

such that

$$\hat{H} |\Psi_p\rangle = \varepsilon_p |\Psi_p\rangle. \quad (6.3)$$

The Hamiltonian can be rewritten as a double sum over all states using the so-called *completeness relation*,

$$\hat{H} = \sum_{ij} |\Phi_i\rangle \langle \Phi_i | \hat{H} | \Phi_j \rangle \langle \Phi_j| \quad (6.4)$$

such that the Schrödinger equation can be rewritten as

$$\begin{pmatrix} \langle \Phi_0 | \hat{H} | \Phi_0 \rangle & \langle \Phi_0 | \hat{H} | \Phi_1 \rangle & \dots & \langle \Phi_0 | \hat{H} | \Phi_{N-1} \rangle \\ \langle \Phi_1 | \hat{H} | \Phi_0 \rangle & \langle \Phi_1 | \hat{H} | \Phi_1 \rangle & \dots & \langle \Phi_1 | \hat{H} | \Phi_{N-1} \rangle \\ \vdots & \vdots & \ddots & \vdots \\ \langle \Phi_{N-1} | \hat{H} | \Phi_0 \rangle & \langle \Phi_{N-1} | \hat{H} | \Phi_1 \rangle & \dots & \langle \Phi_{N-1} | \hat{H} | \Phi_{N-1} \rangle \end{pmatrix} \begin{pmatrix} c_0^{(p)} \\ c_1^{(p)} \\ \vdots \\ c_{N-1}^{(p)} \end{pmatrix} = \varepsilon_p \begin{pmatrix} c_0^{(p)} \\ c_1^{(p)} \\ \vdots \\ c_{N-1}^{(p)} \end{pmatrix} \quad (6.5)$$

Until now, we have not made any assumptions, such that the equation above will give exact results when all single particle functions are included. The problem is that the matrix scales so badly, the number of Slater determinant that we need to include goes as

$$N_{\text{FCI}} = \binom{N_{\text{single orbitals}}}{N_{\text{electrons}}} \quad (6.6)$$

which is exploding. This is quite annoying since we in principle know how to solve the problems exact.

## 6.2 Coupled Cluster

The coupled cluster method is the *de facto* standard wave function-based method for electronic structure calculations. [10] The method approximates the wave function with an exponential expansion,

$$|\Psi_{\text{CC}}\rangle = e^{\hat{T}} |\Phi_0\rangle \quad (6.7)$$

where  $\hat{T}$  is the cluster operator, entirely given by  $\hat{T} = \hat{T}_1 + \hat{T}_2 + \hat{T}_3 + \dots$  with

$$\hat{T}_n = \left( \frac{1}{n!} \right)^2 \sum_{abc\dots} \sum_{ijk\dots} t_{ijk\dots}^{abc\dots} a_a^\dagger a_b^\dagger a_c^\dagger \dots a_k a_j a_i. \quad (6.8)$$

We again want to solve the Schrödinger equation,

$$\hat{H} |\Psi\rangle = \hat{H} e^{\hat{T}} |\Phi_0\rangle = \epsilon e^{\hat{T}} |\Phi_0\rangle, \quad (6.9)$$

which can be simplified by multiplying with  $e^{-\hat{T}}$  from the left. This introduces us to the **similarity transformed Hamiltonian**

$$\bar{H} = e^{-\hat{T}} \hat{H} e^{\hat{T}}. \quad (6.10)$$

If we on one hand now multiply with the reference bra on the left hand side, we easily observe that

$$\langle \Phi_0 | \bar{H} | \Phi_0 \rangle = \epsilon \quad (6.11)$$

which is the coupled cluster energy equation. On the other hand, we can multiply with an excited bra on left hand side, and find that

$$\langle \Phi_{ijk\dots}^{abc\dots} | \bar{H} | \Phi_0 \rangle = 0 \quad (6.12)$$

which are the coupled cluster amplitude equations. The similarity transformed Hamiltonian can be rewritten using the Baker-Campbell-Hausdorff expansion

$$\begin{aligned} \bar{H} &= \hat{H} + [\hat{H}, \hat{T}] \\ &\quad + \frac{1}{2} [[\hat{H}, \hat{T}], \hat{T}] \\ &\quad + \frac{1}{6} [[[[\hat{H}, \hat{T}], \hat{T}], \hat{T}]] \\ &\quad + \frac{1}{24} [[[[[[\hat{H}, \hat{T}], \hat{T}], \hat{T}], \hat{T}], \hat{T}]] \\ &\quad + \dots \end{aligned} \quad (6.13)$$

and we are in principle set to solve the amplitude equations with respect to the amplitudes  $t_{ijk\dots}^{abc\dots}$  and then find the energy. The expansion is able to reproduce the true wave function exactly using a satisfying number of terms and an infinite basis. This is, of course, not possible, but even by limiting us to the first few coupled cluster operators, the results are often good compared to other methods. [12]

# Chapter 7

## Machine Learning

Great quote.

---

Author

Figure 7.1: Caption

The use of the term *machine learning* has exploded over the past years, and sometimes it sounds like it is a totally new field. However, the truth is that many of the methods we use are quite old, where for instance *linear regression* was known early in the 19th century. [1][2] Those methods have just recently been taken under the *machine learning* umbrella, which is one of the reasons why the term is mentioned so often. As the UiO professor Anne Solberg pointed out during one of her lectures

*"In the early 1990's I was working a lot with machine learning, but at that time we called it pattern recognition and regression..."*

Another reason why machine learning has an increasingly popularity is that some of the algorithms have been significantly improved. *Convolutional Neural Networks* (CNNs)

are now as good as humans when it comes to object recognition in images, and *Long Short-Term Memory Recurrent Neural Networks* (LSTM RNNs) has improved voice recognition.

We can conclude that Machine learning includes all methods where we want to fit models to data sets, and pattern recognition and regression are clearly some of those methods. In both cases we have concrete targets for the training, and the training is therefore called supervised training. In other cases we do not have targets, but want to train our model based on a probability distribution or so, which is called unsupervised learning.

## 7.1 Supervised Learning

In supervised learning methods, the input data has known targets such that we can fit a model to give the correct outputs. Linear regression is perhaps the most intuitive example on this, where we want to find the line that fits some data points in the best possible way. This corresponds to a neural network without any hidden layer, but when we add more layers the model is no longer linear and it all gets more complex. For simple classification tasks, logistic regression can be used.

### 7.1.1 Linear regression

In linear regression, the dependent variable  $y_i$  is a linear combination of the parameters, and for a dependent variable this can be written as

$$y_i = \sum_j X_{ij} \beta_j \quad (7.1)$$

where  $\beta_j$ 's are the unknown parameters to be found. In principle,  $X_{ij}$  can be an arbitrary function of the arguments  $x_i$ , but often one wants a polynomial model which corresponds to  $X_{ij} = x_i^j$ .

The three most commonly used linear regression methods are Ordinary Least Square (OLS) regression, Ridge regression and Lasso regression, where the former has the cost function

$$c(\vec{\beta}) = \sum_{i=1}^n \left( y_i - \beta_0 - \sum_{j=1}^p X_{ij} \beta_j \right)^2 \quad \text{OLS,} \quad (7.2)$$

which is minimized when

$$\vec{\beta} = (\hat{X}^T \hat{X})^{-1} \hat{X}^T \vec{y}. \quad (7.3)$$

Similarly, the Ridge cost function is

$$c(\vec{\beta}) = \sum_{i=1}^n \left( y_i - \beta_0 - \sum_{j=1}^p X_{ij} \beta_j \right)^2 + \lambda \sum_{j=1}^p \beta_j^2 \quad \text{Ridge} \quad (7.4)$$

where  $\lambda$  is called the penalty. This is minimized when

$$\vec{\beta} = (\hat{X}^T \hat{X} + \lambda I)^{-1} \hat{X}^T \vec{y}, \quad (7.5)$$

and finally the Lasso cost function is given by

$$c(\vec{\beta}) = \sum_{i=1}^n \left( y_i - \beta_0 - \sum_{j=1}^p X_{ij} \beta_j \right)^2 + \lambda \sum_{j=1}^p \beta_j \quad \text{Lasso.} \quad (7.6)$$

### 7.1.2 Logistic regression

Despite its name, logistic regression is not a fitting tool, but rather a classification tool. Traditionally, the perceptron model was used for 'hard classification', which sets the outputs directly to binary values. However, often we are interested in the probability of a given category, which means that we need a continuous *activation function*. Logistic regression can, like linear regression, be considered as a function where coefficients are adjusted with the intention to minimize the error. Here, the coefficients are called *weights*. The process goes like this: The inputs are multiplied by several weights, and by adjusting those weights the model can classify every *linear classification problem*. A drawing of the perceptron is found in figure (7.2).

Figure 7.2: Logistic regression model with  $n$  inputs.

In logistic regression, we usually have one binary output node for each class, but for two categories one output node is sufficient, which can be fired or not fired.

Initially, one needs to train the perceptron such that it knows which outputs are correct, and for that one needs to know the outputs that correspond to the inputs. Every time the network is trained, the weights are adjusted such that the error is minimized.

The very first step is to calculate the initial outputs (forward phase), where the weights usually are set to small random numbers. Then the error is calculated, and the weights are updated to minimize the error (backward phase). So far so good.

#### 7.1.2.1 Forward phase

Let us look at it from a mathematical perspective, and calculate the net output. The net output seen from an output node is simply the sum of all the "arrows" that point towards the node, see figure (7.2), where each "arrow" is given by the left-hand node multiplied with its respective weight. For example, the contribution from input node 2 to the output node follows from  $X_2 \cdot w_2$ , and the total net output to the output  $O$  is therefore

$$net = \sum_{i=1}^I x_i \cdot w_i + b \cdot 1. \quad (7.7)$$

Just some notation remarks:  $x_i$  is the value of input node  $i$  and  $w_i$  is the weight which connects input  $i$  to the output.  $b$  is the bias weight, which we will discuss later.

You might wonder why we talk about the net output all the time, do we have other outputs? If we look at the network mathematically, what we talk about as the net output

should be our only output. Anyway, it turns out to be convenient mapping the net output to a final output using an activation function, which is explained further in section 7.1.2.5. The activation function,  $f$ , takes in the net output and gives the output,

$$out = f(net). \quad (7.8)$$

If not everything is clear right now, it is fine. We will discuss the most important concepts before we dive into the maths.

### 7.1.2.2 BIAS

As mentioned above, we use biases when calculating the outputs. The nodes, with value  $B$ , are called the bias nodes, and the weights,  $b$ , are called the bias weights. But why do we need those?

Suppose we have two inputs of value zero, and one output which should not be zero (this could for instance be a NOR gate). Without the bias, we will not be able to get any other output than zero, and in fact the network would struggle to find the right weights even if the output had been zero.

The bias value  $B$  does not really matter since the network will adjust the bias weights with respect to it, and is usually set to 1 and ignored in the calculations. [2]

### 7.1.2.3 Learning rate

In principle, the weights could be updated without adding any learning rate ( $\eta = 1$ ), but this can in practice be problematic. It is easy to imagine that the outputs can be fluctuating around the targets without decreasing the error, which is not ideal, and a learning rate can be added to avoid this. The downside is that with a low learning rate the network needs more training to obtain the correct results (and it takes more time), so we need to find a balance.

### 7.1.2.4 Cost function

The cost function is what defines the error, and in logistic regression the cross-entropy function is a naturally choice. [3] It reads

$$c(\mathbf{W}) = - \sum_{i=1}^n \left[ y_i \log f(\mathbf{x}_i^T \mathbf{W}) + (1 - y_i) \log[1 - f(\mathbf{x}_i^T \mathbf{W})] \right] \quad (7.9)$$

where  $\mathbf{W}$  contains all weights, included the bias weight ( $\mathbf{W} \equiv [b, \mathbf{W}]$ ), and similarly does  $\mathbf{x}$  include the bias node, which is 1;  $\mathbf{x} \equiv [1, \mathbf{x}]$ . Further, the  $f(x)$  is the activation function discussed in next section.

The cross-entropy function is derived from likelyhood function, which famously reads

$$p(y|x) = \hat{y}^y \cdot (1 - \hat{y})^{1-y}. \quad (7.10)$$

Working in the log space, we can define a log likelyhood function

$$\log [p(y|x)] = \log [\hat{y}^y \cdot (1 - \hat{y})^{1-y}] \quad (7.11)$$

$$= y \log \hat{y} + (1 - y) \log(1 - \hat{y}) \quad (7.12)$$

which gives the log of the probability of obtaining  $y$  given  $x$ . We want this quantity to increase then the cost function is decreased, so we define our cost function as the negative log likelihood function. [7]

Additionally, including a regularization parameter  $\lambda$  inspired by Ridge regression is often convenient, such that the cost function is

$$c(\mathbf{W})^+ = c(\mathbf{W}) + \lambda \|\mathbf{W}\|_2^2. \quad (7.13)$$

We will later study how this regularization affects the classification accuracy.

### 7.1.2.5 Activation function

Above, we were talking about the activation function, which is used to activate the net output. In binary models, this is often just a step function firing when the net output is above a threshold. For continuous outputs, the logistic function given by

$$f(x) = \frac{1}{1 + e^{-x}}. \quad (7.14)$$

is usually used in logistic regression to return a probability instead of a binary value. This function has a simple derivative, which is advantageous when calculating a large number of derivatives. As shown in section ??, the derivative is simply

$$\frac{df(x)}{dx} = x(1 - x). \quad (7.15)$$

$\tanh(x)$  is another popular activation function in logistic regression, which more or less holds the same properties as the logistic function.

### 7.1.2.6 Backward phase

Now all the tools for finding the outputs are in place, and we can calculate the error. If the outputs are larger than the targets (which are the exact results), the weights need to be reduced, and if the error is large the weights need to be adjusted a lot. The weight adjustment can be done by any minimization method, and we will look at a couple of gradient methods. To illustrate the point, we will stick to the **gradient descent** (GD) method in the calculations, even though other methods will be used later. The principle of GD is easy: each weight is "moved" in the direction of steepest slope,

$$\mathbf{w}^+ = \mathbf{w} - \eta \cdot \frac{\partial c(\mathbf{w})}{\partial \mathbf{w}}, \quad (7.16)$$

where  $\eta$  is the learning rate and  $c(\mathbf{w})$  is the cost function. We use the chain rule to simplify the derivative

$$\frac{\partial c(\mathbf{w})}{\partial \mathbf{w}} = \frac{\partial c(\mathbf{w})}{\partial out} \cdot \frac{\partial out}{\partial net} \cdot \frac{\partial net}{\partial \mathbf{w}} \quad (7.17)$$

where the first is the derivative of the cost function with respect to the output. For the cross-entropy function, this is

$$\frac{\partial c(\mathbf{w})}{\partial out} = -\frac{y}{out} + \frac{1 - y}{1 - out}. \quad (7.18)$$

Further, the second derivative is the derivative of the activation function with respect to the output, which is given in (7.15)

$$\frac{\partial out}{\partial net} = out(1 - out). \quad (7.19)$$

The latter derivative is the derivative of the net output with respect to the weights, which is simply

$$\frac{\partial net}{\partial \mathbf{w}} = \mathbf{x}. \quad (7.20)$$

If we now recall that  $out = f(\mathbf{x}^T \mathbf{w})$ , we can write

$$\frac{\partial c(\mathbf{w})}{\partial \mathbf{w}} = [f(\mathbf{x}^T \mathbf{w}) - \mathbf{y}] \mathbf{x} \quad (7.21)$$

and obtain a weight update algorithm

$$\mathbf{w}^+ = \mathbf{w} - \eta \cdot [f(\mathbf{x}^T \mathbf{w}) - \mathbf{y}]^T \mathbf{x}. \quad (7.22)$$

where the bias weight is included implicitly in  $\mathbf{w}$  and the same applies for  $\mathbf{x}$ .

### 7.1.3 Neural network

If you have understood logistic regression, understanding a neural network should not be a difficult task. According to **the universal approximation theorem**, a neural network with only one hidden layer can approximate any continuous function. [8] However, often multiple layers are used since this tends to give fewer nodes in total.

In figure (7.3), a two-layer neural network (one hidden layer) is illustrated. It has some similarities with the logistic regression model in figure (7.2), but a hidden layer and multiple outputs are added. In addition, the output is no longer probabilities and can take any number, which means that we do not need to use the logistic function on the outputs anymore.

Figure 7.3: Neural network with 3 input nodes, 5 hidden nodes and 2 output nodes, in addition to the bias nodes.

Without a hidden layer, we have seen that the update of weights is quite straight forward. For a neural network consisting of multiple layers, the question is: how do we

update the weights when we do not know the values of the hidden nodes? And how do we know which layer causing the error? This will be explained in section 7.1.3.3, where one of the most popular techniques for that is discussed. Before that we will generalize the forward phase presented in logistic regression.

### 7.1.3.1 Forward phase

In section 7.1.2.1, we saw how the output is found for a single perceptron. Since we only had one output node, the weights could be stored in an array. Generally, it is more practical to store the weights in matrices, since they will have indices related to both the node on left-hand side and the node on the right-hand side. For instance, the weight between input node  $x_3$  and hidden node  $h_5$  in figure (7.3) is usually labeled as  $w_{35}$ . Since we have two layers, we also need to denote which weight set it belongs to, which we will do by a superscript ( $w_{35} \Rightarrow w_{35}^{(1)}$ ). In the same way,  $\mathbf{W}^1$  is the matrix containing all  $w_{ij}^{(1)}$ ,  $\mathbf{x}$  is the vector containing all  $x_i$ 's and so on. We then find the net outputs at the hidden layer to be

$$net_{h,j} = \sum_{i=1}^I x_i \cdot w_{ij}^{(1)} = \mathbf{x}^T \mathbf{W}_j^{(1)} \quad (7.23)$$

where the  $\mathbf{x}$  and  $\mathbf{W}^{(1)}$  again are understood to take the biases. This will be the case henceforth. The real output to the hidden nodes will be

$$h_j = f(net_{h,j}). \quad (7.24)$$

Further, we need to find the net output to the output nodes, which is obviously just

$$net_{o,j} = \sum_{i=1}^H h_i \cdot w_{ij}^{(2)} = \mathbf{h}^T \mathbf{W}_j^{(2)} \quad (7.25)$$

We can easily generalize this. Looking at the net output to a hidden layer  $l$ , we get

$$\mathbf{net}_{h_l} = \mathbf{h}^{(l-1)T} \mathbf{W}^{(l)}. \quad (7.26)$$

### 7.1.3.2 Activation function

Before 2012, the logistic, the tanh and the pure linear functions were the standard activation functions, but then Alex Krizhevsky published an article where he introduced a new activation function called *Rectified Linear Units (ReLU)* which outperformed the classical activation functions. [4] The network he used is now known as AlexNet, and helped to revolutionize the field of computer vision. [5] After that, the ReLU activation function has been modified several times (avoiding zero derivative among others), and examples of innovations are *leaky ReLU* and *Exponential Linear Unit (ELU)*. All those networks are linear for positive numbers, and small for negative numbers. Often, especially in the output layer, a straight linear function is used as well.

In figure (??), *standard ReLU*, *leaky ReLU* and *ELU* are plotted along with the logistic function.

### 7.1.3.3 Backward Propagation

Backward propagation is probably the most used technique for updating the weights, and is actually again based on equation (7.16). What differs, is the differentiation of the net input with respect to the weight, which gets more complex as we add more layers. For one hidden layer, we have two sets of weights, where the last layer is updated in a similar way as for a network without hidden layer, but the inputs are replaced with the values of the hidden nodes:

$$w_{ij}^{(2)+} = w_{ij}^{(2)} - \eta \cdot [f(h_i^T w_{ij}) - y_j]^T h_i. \quad (7.27)$$

We recognize the first part as  $\delta_{ok}$ , such that

$$w_{ij}^{(1)+} = w_{ij}^{(1)} - \eta \cdot \sum_{k=1}^O \delta_{ok} \cdot w_{jk}^{(2)} \cdot f'(out_{hj}) \cdot x_i \quad (7.28)$$

where we recall  $\delta_{ok}$  as

$$\delta_{ok} = -(t_{ok} - out_{ok}) \cdot f'(out_{ok}).$$

For more layers, the procedure is the same, but we keep on inserting the obtained outputs from various layers.

### 7.1.3.4 Summary

Since it will be quite a lot calculations, I will just express the results here, and move the calculations to Appendix B. The forward phase in a three-layer perceptron is

$$\begin{aligned} net_{hi} &= \sum_j w_{ji}^{(1)} \cdot x_j \\ out_{hi} &= f(net_{hi}) \\ net_{ki} &= \sum_j w_{ji}^{(2)} \cdot out_{hj} \\ out_{ki} &= f(net_{ki}) \\ net_{oi} &= \sum_j w_{ji}^{(3)} \cdot out_{kj} \\ out_{oi} &= f(net_{oi}) \end{aligned} \quad (7.29)$$

which can easily be turned into vector form. The backward propagation follows from the two-layer example, and we get

$$\begin{aligned} w_{ij}^{(3)} &= w_{ij}^{(3)} - \eta \cdot \delta_{oj} \cdot out_{ki} \\ w_{ij}^{(2)} &= w_{ij}^{(2)} - \eta \sum_{k=1}^O \delta_{ok} \cdot w_{jk}^{(3)} \cdot f'(out_{kj}) \cdot out_{hi} \\ w_{ij}^{(1)} &= w_{ij}^{(1)} - \eta \sum_{k=1}^O \sum_{l=1}^K \delta_{ok} \cdot w_{lk}^{(3)} \cdot f'(out_{kl}) \cdot w_{jl}^{(2)} f'(out_{hj}) \cdot x_i \end{aligned}$$

where we again use the short hand

$$\delta_{oj} = (t_j - out_{oj}) \cdot f'(out_{oj}).$$

If we compare with the weight update formulas for the two-layer case, we recognize some obvious connections, and it is easy to imagine how we can construct a general weight update algorithm, no matter how many layers we have.

Now over to the problem we want to solve using neural networks.

## 7.2 Unsupervised Learning

How can we train using unsupervised learning?

### 7.2.1 Statistical foundation

Bayesian statistics

### 7.2.2 Boltzmann Machines

Boltzmann Machines are based on the more primitive Hopfield network, where a system of nodes is set up which defines the system energy. Inspired by statistical mechanics, the probability of finding the system in a state of energy  $E$  is given by

$$P = \exp(-E/kT) \quad (7.30)$$

which is the Boltzmann distribution, hence the name Boltzmann machine.  $k$  is known as Boltzmann's constant and  $T$  is the system temperature, but henceforth they both will be avoided by scaling  $E' = E/kT$ .

In the most general form, all nodes are connected to all other nodes, that is an unrestricted Boltzmann machine, see figure (7.4) for illustration.

Figure 7.4: Unrestricted Boltzmann machine. Black lines are connections between all the nodes, where for instance the line between  $s_1$  and  $s_6$  is related to the weight  $w_{16}$ . The blue lines are related to the bias weights, and, for instance, the line going from the bias node to  $s_3$  is related to  $b_3$ .

In the same manner as for a feed-forward neural network, we can directly multiply each node  $s_i$  with all its respective inner weights  $w_{ij}$  and then with the other nodes  $s_j$ .

To obtain the total system energy, we also need to include the bias weights, i.e, multiply  $s_i$  with  $b_i$ . This gives the energy

$$E(\mathbf{s}) = - \sum_{i=1}^N s_i b_i - \sum_{i=1}^N \sum_{j=i}^N s_i w_{ij} s_j \quad (7.31)$$

for a system of  $N$  nodes, which is the so-called binary-binary network and the most basic architecture. During training, the weights are adjusted in order to maximize the probability...

### 7.2.3 Restricted Boltzmann machines

When there is an unrestricted guy, a restricted guy must exist as well. What the term restricted means in this case, is that we ignore intra-layer connections and keep only the inter-layer ones. In the same manner as in equation (7.31), we can look at the linear case, where each node is multiplied with the corresponding weight. We decide to split the bias nodes into one part connected to the *visible* layer,  $a_i$ , and one part connected to the *hidden* layer,  $b_i$ . The system energy then reads

$$E(\mathbf{x}, \mathbf{h}) = - \sum_{i=1}^F x_i a_i - \sum_{j=1}^H h_j b_j - \sum_{i=1}^F \sum_{j=1}^H x_i w_{ij} h_j \quad (7.32)$$

which is the simplest type of units.  $F$  is the number of visible nodes and  $H$  is number of hidden nodes. The neural network is illustrated in figure (7.5)

Figure 7.5: Restricted Boltzmann machine. Black lines the inter-layer connections, where for instance the line between  $x_1$  and  $h_1$  is related to the weight  $w_{11}$ . The blue lines are related to the input bias weights, and, for instance, the line going from the bias node to  $x_3$  is related to  $a_3$ . Similarly, the green lines are related to the hidden nodes bias weights, and, for instance, the line going from the bias node to  $h_3$  is related to  $b_3$ .

We can also take more complicated types of units into account than the binary-binary. A natural next step is the Gaussian-binary units, which has a Gaussian mapping between the visible node bias and the visible nodes. The simplest such structure gives the following system energy:

$$E(\mathbf{x}, \mathbf{h}) = \sum_{i=1}^F \frac{(x_i - a_i)^2}{2\sigma_i^2} - \sum_{j=1}^H h_j b_j - \sum_{i=1}^F \sum_{j=1}^H \frac{x_i w_{ij} h_j}{\sigma_i^2} \quad (7.33)$$

where  $\sigma_i$  is the width of the Gaussian distribution, which can be set to an arbitrary number.

$$\Psi(\mathbf{x}; \mathbf{a}, \mathbf{b}, \mathbf{W}) = \exp\left(-\sum_{i=1}^F \frac{(x_i - a_i)^2}{2\sigma_i^2}\right) \prod_{j=1}^H \left(1 + \exp\left(b_j + \sum_{i=1}^F \frac{w_{ij} x_i}{\sigma_i^2}\right)\right) \quad (7.34)$$

Need to compare it to standard VMC with Padé-Jastrow factor.

### 7.2.4 Partly restricted Boltzmann machine

One can also imagine a partly restricted architecture, where we have inter-layer connections between the visible nodes, but not the hidden nodes. This is what we have decided to call a partly restricted Boltzmann machine.

Figure 7.6: Partly restricted Boltzmann machine. Black lines are inter-layer connections, where for instance the line between  $x_1$  and  $h_1$  is related to the weight  $w_{11}$ . The blue lines are related to the input bias weights, and, for instance, the line going from the bias node to  $x_3$  is related to  $a_3$ . Similarly, the green lines are related to the hidden nodes bias weights, and, for instance, the line going from the bias node to  $h_3$  is related to  $b_3$ . Finally, the red lines are the intra-layer connections related to the intra-layer weights. The weight between node  $x_1$  and  $x_2$  is called  $c_{12}$ .

$$E(\mathbf{x}, \mathbf{h}) = \sum_{i=1}^F \frac{(x_i - a_i)^2}{2\sigma_i^2} - \sum_{i=1}^F \sum_{j=1}^F x_i c_{ij} x_j - \sum_{j=1}^H h_j b_j - \sum_{i=1}^F \sum_{j=1}^H \frac{x_i w_{ij} h_j}{\sigma_i^2} \quad (7.35)$$

$$\Psi(\mathbf{x}; \mathbf{a}, \mathbf{b}, \mathbf{W}) = \exp\left(-\sum_{i=1}^F \frac{(x_i - a_i)^2}{2\sigma_i^2} + \sum_{i=1}^F \sum_{j=1}^F x_i c_{ij} x_j\right) \prod_{j=1}^H \left(1 + \exp\left(b_j + \sum_{i=1}^F \frac{w_{ij} x_i}{\sigma_i^2}\right)\right) \quad (7.36)$$

# Chapter 8

## Derivation of Wave Function Elements

In chapter (2) we presented the basic principles behind a many-body trial wave function, including the Slater determinant and the well-known Padé-Jastrow factor. Further, in chapter (3), the common basis functions of the harmonic oscillator and atomic systems were given, and in the previous chapter, (7), we explained how to create wave functions using machine learning. This means that all wave function elements used in this thesis already are given, and in this chapter they are all collected, together with their derivatives and various optimizations. The calculations below are based on two main assumptions:

- For each step, we move one particle in one direction.
- A variational parameter occurs in only one of the wave function elements.

The first assumption is necessary when we calculate the ratio between the new and the old wave function used in Metropolis sampling, and we need the last to simplify the update of parameters. We start with splitting up the kinetic energy calculations and parameter update to see which derivatives we need.

### 8.1 Kinetic Energy Calculations

The local energy, defined in equation (4.5), is

$$E_L = \frac{1}{\Psi_T} \hat{H} \Psi_T \quad (8.1)$$

$$= \sum_{k=1}^M \left[ -\frac{1}{2\Psi_T} \nabla_k^2 \Psi_T + U_k + V_k \right]. \quad (8.2)$$

The first term, which is the kinetic energy term, is the only wave function-dependent one. It will in this chapter be evaluated for various wave function elements. From the definition of differentiation of a logarithm, we have that

$$\frac{1}{\Psi_T} \nabla_k \Psi_T = \nabla_k \ln \Psi_T, \quad (8.3)$$

which provides the following useful relation

$$\frac{1}{\Psi_T} \nabla_k^2 \Psi_T = \nabla_k^2 \ln \Psi_T + (\nabla_k \ln \Psi_T)^2. \quad (8.4)$$

Consider a trial wave function,  $\Psi_T$ , consisting of a product of  $p$  wave function elements,  $\{\phi_1, \phi_2 \dots \phi_p\}$ ,

$$\Psi_T = \prod_{i=1}^p \phi_i. \quad (8.5)$$

The kinetic energy related to this trial wave function is then computed by

$$\frac{1}{\Psi_T} \nabla_k^2 \Psi_T = \sum_{i=1}^p \nabla_k^2 \ln \phi_i + \left( \sum_{i=1}^p \nabla_k \ln \phi_i \right)^2, \quad (8.6)$$

which can be found when all local derivatives  $\nabla_k^2 \ln \phi_i$  and  $\nabla_k \ln \phi_i$  are given. For each wave function element given below, those local derivatives will be evaluated. In addition, we need to know the derivative of the local energy with respect to the variational parameters in order to update the parameters correctly.

## 8.2 Parameter Update

In gradient based optimization methods, as we use, one needs to know the gradient of the local energy with respect to all variational parameters  $\alpha_i$ ,

$$\partial_{\alpha_i} \langle E_L \rangle \equiv \frac{\partial \langle E_L(\alpha_i) \rangle}{\partial \alpha_i}. \quad (8.7)$$

Since we are dealing with an expectation value, this gradient can be found from

$$\partial_{\alpha_i} \langle E_L \rangle = 2 \left( \langle E_L \partial_{\alpha_i} \ln \Psi_T \rangle - \langle E_L \rangle \langle \partial_{\alpha_i} \ln \Psi_T \rangle \right) \quad (8.8)$$

which means that we need to calculate the expectation values  $\langle E_L \partial_{\alpha_i} \ln \Psi_T \rangle$  and  $\langle \partial_{\alpha_i} \ln \Psi_T \rangle$  in addition to the local energy, which is done by Monte-Carlo integration.

## 8.3 Optimizations

How much a wave function element can be optimized heavily depends on the specific form of the element. For instance, sometimes the previous and present  $\nabla_k \ln \phi_i$  are closely related, and only differ with a few calculations, while for some other elements they are not related at all. Those subjective optimizations will therefore be described when presenting each wave function element.

However, there are still optimizations that apply to all elements and give great speed-up. An example is to calculate the ratio between the previous and present wave functions for all wave function elements instead of the wave function itself. Firstly, this is usually cheaper to calculate than the wave function because we are living in the logarithmic space. Secondly, the ratio is actually what we use in the sampling, so it is a natural thing to calculate. The total wave function ratio is just the product of all the wave function element ratios

$$\frac{\Psi_T^{\text{new}}}{\Psi_T^{\text{old}}} = \prod_{i=1}^p \frac{\phi_i^{\text{new}}}{\phi_i^{\text{old}}}.$$

## 8.4 Derivatives

### 8.4.1 Simple Gaussian

A natural starting point is the Gaussian function, since it appears in traditional variational Monte-Carlo computations of the harmonic oscillator. It is also quite simple to evaluate both in Cartesian and spherical coordinates. We are interested in the former. For  $M$  free dimensions, the function is given by

$$\Psi(\mathbf{x}; \alpha) = \exp \left( -\frac{1}{2} \omega \alpha \sum_{i=1}^M x_i^2 \right)$$

where the gradient with respect to coordinate  $x_k$  is

$$\nabla_k \ln \Psi(\alpha) = -\omega \alpha x_k$$

and the corresponding Laplacian is

$$\nabla_k^2 \ln \Psi(\alpha) = -\omega \alpha.$$

Finally, for the parameter update, we have that

$$\partial_\alpha \ln \Psi = -\frac{1}{2} \omega \sum_{i=1}^M x_i^2. \quad (8.9)$$

The most natural thing to The only thing that can be optimized regarding this element, is the ratio between the new and the old probability. All expressions are collected below

$$\begin{aligned} \frac{\Psi_{\text{new}}^2}{\Psi_{\text{old}}^2} &= \exp \left( \alpha \omega (x_{i,\text{old}}^2 - x_{i,\text{new}}^2) \right) \\ \nabla_k \ln \Psi &= -\omega \alpha x_k \\ \nabla_k^2 \ln \Psi &= -\omega \alpha \\ \partial_\alpha \ln \Psi &= -\frac{1}{2} \omega \sum_{i=1}^M x_i^2, \end{aligned} \quad (8.10)$$

where  $i$  is the changed coordinate. Since the final expressions are all neat, there are no further optimizations available.

### 8.4.2 Padé-Jastrow Factor

The Padé-Jastrow factor is introduced in order to take care of the correlations. It is specified in equation (2.15),

$$J(\mathbf{r}; \beta, \gamma) = \exp \left( \sum_{i=1}^P \sum_{j=1}^P \frac{a_{ij} r_{ij}}{1 + \beta r_{ij}} \right),$$

where  $N$  is the number of particles. One challenge is that we operate in cartesian coordinates, while the expressed Jastrow factor obviously is easier to handle in spherical coordinates. Since we need to differentiate this with respect to all free dimensions, we

need to be careful not to confuse the particle indices and coordinate indices. Let us define  $i$  as the coordinate index and  $i'$  as the index on the corresponding particle. We then get the first and second derivatives

$$\nabla_k \ln J = \sum_{j' \neq k'=1}^P \frac{\beta_{k'j'}}{(1 + \gamma r_{k'j'})^2} \frac{x_k - x_j}{r_{k'j'}}$$

and

$$\nabla_k^2 \ln J = \sum_{j' \neq k'=1}^P \frac{\beta_{k'j'}}{(1 + \gamma r_{k'j'})^2} \left[ 1 - \left( 1 + 2 \frac{\gamma r_{k'j'}}{1 + \gamma r_{k'j'}} \right) \frac{(x_k - x_j)^2}{r_{k'j'}^2} \right] \frac{1}{r_{k'j'}}$$

respectively, where  $j$  yields the same dimension as  $k$ .

The derivative of those again with respect to  $\gamma$  are

$$\partial_\gamma \nabla_k \ln J = -2 \sum_{j' \neq k'=1}^P \frac{\beta_{k'j'}}{(1 + \gamma r_{k'j'})^3} (x_k - x_j)$$

and

$$\partial_\gamma \nabla_k^2 \ln J = -2 \sum_{j' \neq k'=1}^P \frac{\beta_{k'j'}}{(1 + \gamma r_{k'j'})^3} \left[ 1 - 4 \frac{\gamma r_{k'j'}}{1 + \gamma r_{k'j'}} \frac{(x_k - x_j)^2}{r_{k'j'}^2} \right]$$

By defining

$$f_{ij} = \frac{1}{1 + \gamma r_{ij}} \quad g_{ij} = \frac{x_i - x_j}{r_{ij}} \quad h_{ij} = \frac{r_{ij}}{1 + \gamma r_{ij}}$$

the equations can be written as

$$\begin{aligned} \frac{J_{\text{new}}^2}{J_{\text{old}}^2} &= \exp \left( 2 \sum_{j'=1}^N \beta_{i'j'} (h_{i'j'}^{\text{new}} - h_{i'j'}^{\text{old}}) \right) \\ \nabla_k \ln J &= \sum_{j' \neq k'=1}^N \beta_{k'j'} \cdot f_{k'j'}^2 \cdot g_{kj} \\ \nabla_k^2 \ln J &= \sum_{j' \neq k'=1}^N \frac{\beta_{k'j'}}{r_{k'j'}} f_{k'j'}^2 \left[ 1 - (1 + 2\gamma h_{k'j'}) g_{kj}^2 \right] \\ \partial_\gamma \nabla_k \ln J &= \sum_{j' \neq k'=1}^N \beta_{k'j'} \cdot f_{k'j'}^3 (x_k - x_j) \\ \partial_\gamma \nabla_k^2 \ln J &= \sum_{j' \neq k'=1}^N \beta_{k'j'} \cdot f_{k'j'}^3 \left[ 1 - 4\gamma h_{k'j'} \cdot g_{kj}^2 \right], \end{aligned} \tag{8.11}$$

with marked indices ( $i'$ ) as the particle related ones and the unmarked ( $i$ ) as the coordinate related ones.  $i'$  is the moved particle.

### 8.4.3 Slater Determinant

As described in section (2.2.2), the Slater determinant can be split up in a spin-up part and a spin-down part,

$$\Psi(\mathbf{x}) = |\hat{D}_\uparrow(\mathbf{x}_\uparrow)| \cdot |\hat{D}_\downarrow(\mathbf{x}_\downarrow)|$$

where  $x_\uparrow$  are the coordinates of particles with spin up (defined as the first half of the coordinates) and  $x_\downarrow$  are the coordinates of particles with spin down (defined as the last half of the coordinates).

We can now utilize the logarithmic scale,

$$\ln \Psi = \ln |\hat{D}_\uparrow(\mathbf{x}_\uparrow)| + \ln |\hat{D}_\downarrow(\mathbf{x}_\downarrow)|$$

such that we only need to care one of the determinants when differentiating, dependent on whether the coordinate we differentiate with respect to is among the spin-up or the spin-down coordinates:

$$\nabla_k \ln \Psi = \begin{cases} \nabla_k \ln |\hat{D}_\uparrow(\mathbf{x}_\uparrow)| & \text{if } k < M/2 \\ \nabla_k \ln |\hat{D}_\downarrow(\mathbf{x}_\downarrow)| & \text{if } k \geq M/2. \end{cases}$$

Before we go further, we will therefore introduce a more general notation which cover both cases:

$$\hat{D} \equiv \hat{D}_\sigma(\mathbf{x}_\sigma)$$

where  $\sigma$  is the spin. When summing, the sum is always over all relevant coordinates.

Furthermore, we have that

$$\nabla_k \ln |\hat{D}| = \frac{\nabla_k |\hat{D}|}{|\hat{D}|}$$

and

$$\nabla_k^2 \ln |\hat{D}| = \frac{\nabla_k^2 |\hat{D}|}{|\hat{D}|} - \left( \frac{\nabla_k |\hat{D}|}{|\hat{D}|} \right)^2$$

The first derivative of a determinant is given by Jacobi's formula, which reads

$$\frac{\nabla_i |\hat{A}|}{|\hat{A}|} = \text{tr}(\hat{A}^{-1} \nabla_i \hat{A}), \quad (8.12)$$

and the second derivative is then

$$\frac{\nabla_i^2 |\hat{A}|}{|\hat{A}|} = \left[ \left( \text{tr}(\hat{A}^{-1} \nabla_i \hat{A}) \right)^2 + \text{tr}(\hat{A}^{-1} \nabla_i^2 \hat{A}) - \text{tr}(\hat{A}^{-1} \nabla_i \hat{A} \hat{A}^{-1} \nabla_i \hat{A}) \right]$$

where  $\text{tr}(\hat{B})$  is the trace of matrix  $\hat{B}$ , i.e, the sum of all diagonal elements.

We continue writing the trace as a sum, such that

$$\text{tr}(\hat{A}^{-1} \nabla_i \hat{A}) = \sum_{j=1}^N A_{ji}^{-1} \nabla_i A_{ij}$$

and

$$\text{tr}(\hat{A}^{-1} \nabla_i^2 \hat{A}) = \sum_{j=1}^N A_{ji}^{-1} \nabla_i^2 A_{ij}.$$

In the end, we will take advantage of the fact that we only move one particle at a time. This means one of the two determinants cancel when calculating the probability ratio used in Metropolis sampling. Since we do not have any variational parameters in the Slater determinant, we end up with three expressions for each determinant:

$$\begin{aligned}
& \text{if } k < M/2 : \\
& \frac{|\Psi_{\text{new}}|^2}{|\Psi_{\text{old}}|^2} = |\hat{D}_{\uparrow}(\mathbf{x}_{\uparrow}^{\text{new}})|^2 / |\hat{D}_{\uparrow}(\mathbf{x}_{\uparrow}^{\text{old}})|^2 \\
& \nabla_k \ln |\hat{D}_{\uparrow}| = \sum_{j=1}^{M/2} \nabla_k d_{jk} d_{kj}^{-1} \\
& \nabla_k^2 \ln |\hat{D}_{\uparrow}| = \sum_{j=1}^{M/2} \nabla_k^2 d_{jk} d_{kj}^{-1} - \left( \sum_{j=1}^{M/2} \nabla_k d_{ik} d_{ki}^{-1} \right)^2
\end{aligned} \tag{8.13}$$

$$\begin{aligned}
& \text{if } k \geq M/2 : \\
& \frac{|\Psi_{\text{new}}|^2}{|\Psi_{\text{old}}|^2} = |\hat{D}_{\downarrow}(\mathbf{x}_{\downarrow}^{\text{new}})|^2 / |\hat{D}_{\downarrow}(\mathbf{x}_{\downarrow}^{\text{old}})|^2 \\
& \nabla_k \ln |\hat{D}_{\downarrow}| = \sum_{j=M/2}^M \nabla_k d_{jk} d_{kj}^{-1} \\
& \nabla_k^2 \ln |\hat{D}_{\downarrow}| = \sum_{j=M/2}^M \nabla_k^2 d_{jk} d_{kj}^{-1} - \left( \sum_{j=M/2}^M \nabla_k d_{ik} d_{ki}^{-1} \right)^2
\end{aligned} \tag{8.14}$$

#### 8.4.3.1 Efficient calculation of Slater determinants

As you might already have noticed, we need to calculate the inverse of the matrices every time a particle is moved. This is a pretty heavy task for the computer, where the standard way, LU decomposition, gives  $\sim N^3$  floating point operations (FLOPS). [11].

The good thing is that, by exploiting that only one row in the Slater matrix is updated for each step, we can update the inverse iteratively.

#### 8.4.4 NQS-Gaussian

Now over to the real deal; the machine learning inspired wave function elements. The total NQS wave function, presented in equation (7.34), was decided split up in case we wanted to run them separately. The first part will henceforth be denoted as the NQS-Gaussian,

$$\Psi(\mathbf{x}; \mathbf{a}) = \exp \left( - \sum_{i=1}^M \frac{(x_i - a_i)^2}{2\sigma^2} \right) \tag{8.15}$$

while the last part will be denoted as the NQS-Jastrow and is presented in the next subsection.

The derivatives of the NQS-Gaussian are similar to those of the simple Gaussian, they are therefore just listed up in equation (8.16).

$$\begin{aligned}
\frac{\Psi_{\text{new}}^2}{\Psi_{\text{old}}^2} &= \exp \left( (x_i^{\text{old}} + x_i^{\text{new}} - 2a_i)(x_i^{\text{old}} - x_i^{\text{new}}) \right) \\
\nabla_k \ln \Psi &= -\frac{x_k - a_k}{\sigma^2} \\
\nabla_k^2 \ln \Psi &= -\frac{1}{\sigma^2} \\
\partial_{a_l} \nabla_k \ln \Psi &= \frac{1}{\sigma^2} \\
\partial_{a_l} \nabla_k^2 \ln \Psi &= 0
\end{aligned} \tag{8.16}$$

#### 8.4.5 NQS-Jastrow Factor

$$\begin{aligned}
J(\mathbf{x}; \mathbf{b}, \mathbf{W}) &= \prod_{j=1}^N \left[ 1 + \exp \left( b_j + \sum_{i=1}^M \frac{W_{ij}x_i}{\sigma^2} \right) \right] \\
\nabla_k \ln J &= \sum_{j=1}^N \frac{W_{kj}}{\sigma^2} \frac{\exp \left( b_j + \sum_{i=1}^M \frac{W_{ij}x_i}{\sigma^2} \right)}{1 + \exp \left( b_j + \sum_{i=1}^M \frac{W_{ij}x_i}{\sigma^2} \right)} \\
\nabla_k^2 \ln J &= \sum_{j=1}^N \frac{W_{kj}^2}{\sigma^4} \frac{\exp \left( b_j + \sum_{i=1}^M \frac{W_{ij}x_i}{\sigma^2} \right)}{\left( 1 + \exp \left( b_j + \sum_{i=1}^M \frac{W_{ij}x_i}{\sigma^2} \right) \right)^2} \\
\partial_{b_l} \nabla_k \ln J &= \frac{W_{kl}}{\sigma^2} \frac{\exp \left( b_l + \sum_{i=1}^M \frac{W_{il}x_i}{\sigma^2} \right)}{\left( 1 + \exp \left( b_l + \sum_{i=1}^M \frac{W_{il}x_i}{\sigma^2} \right) \right)^2} \\
\partial_{b_l} \nabla_k^2 \ln J &= \frac{W_{kl}^2}{\sigma^4} \frac{\exp \left( b_l + \sum_{i=1}^M \frac{W_{il}x_i}{\sigma^2} \right) \left( 1 - \exp \left( b_l + \sum_{i=1}^M \frac{W_{il}x_i}{\sigma^2} \right) \right)}{\left( 1 + \exp \left( b_l + \sum_{i=1}^M \frac{W_{il}x_i}{\sigma^2} \right) \right)^3} \\
\partial_{W_{ml}} \nabla_k \ln J &= \frac{1}{\sigma^2} \frac{\exp \left( b_l + \sum_{i=1}^M \frac{W_{il}x_i}{\sigma^2} \right)}{1 + \exp \left( b_l + \sum_{i=1}^M \frac{W_{il}x_i}{\sigma^2} \right)} \delta_{mk} + \frac{W_{kl}x_m}{\sigma^4} \frac{\exp \left( b_l + \sum_{i=1}^M \frac{W_{il}x_i}{\sigma^2} \right)}{\left( 1 + \exp \left( b_l + \sum_{i=1}^M \frac{W_{il}x_i}{\sigma^2} \right) \right)^2} \\
\partial_{W_{ml}} \nabla_k^2 \ln J &= 2 \frac{W_{kl}}{\sigma^4} \frac{\exp \left( b_l + \sum_{i=1}^M \frac{W_{il}x_i}{\sigma^2} \right)}{\left( 1 + \exp \left( b_l + \sum_{i=1}^M \frac{W_{il}x_i}{\sigma^2} \right) \right)^2} \delta_{mk} + \frac{W_{kl}^2 x_m}{\sigma^4} \frac{\exp \left( b_l + \sum_{i=1}^M \frac{W_{il}x_i}{\sigma^2} \right)}{\left( 1 + \exp \left( b_l + \sum_{i=1}^M \frac{W_{il}x_i}{\sigma^2} \right) \right)^3}
\end{aligned}$$

where  $\delta_{ij}$  is the Kronecker delta. Defining

$$p_j \equiv \frac{1}{1 + \exp \left( b_j + \sum_{i=1}^M \frac{W_{ij}x_i}{\sigma^2} \right)} \quad \text{and} \quad n_j \equiv \frac{1}{1 + \exp \left( -b_j - \sum_{i=1}^M \frac{W_{ij}x_i}{\sigma^2} \right)}$$

the expressions above can be simplified in the following fashion

$$\begin{aligned}
\frac{J_{\text{new}}^2}{J_{\text{old}}^2} &= \prod_{j=1}^N \frac{p_j^{\text{old}}}{p_j^{\text{new}}} \\
\nabla_k \ln J &= \sum_{j=1}^N \frac{W_{kj}}{\sigma^2} n_j \\
\nabla_k^2 \ln J &= \sum_{j=1}^N \frac{W_{kj}^2}{\sigma^4} p_j n_j \\
\partial_{b_l} \nabla_k \ln J &= \frac{W_{kl}}{\sigma^2} p_l n_l \\
\partial_{b_l} \nabla_k^2 \ln J &= \frac{W_{kl}^2}{\sigma^4} p_l n_l (p_l - n_l) \\
\partial_{W_{ml}} \nabla_k \ln J &= \frac{1}{\sigma^2} n_l \delta_{mk} + \frac{W_{kl} x_m}{\sigma^4} p_l n_l \\
\partial_{W_{ml}} \nabla_k^2 \ln J &= 2 \frac{W_{kl}}{\sigma^4} p_l n_l \delta_{mk} + \frac{W_{kl}^2 x_m}{\sigma^6} p_l n_l (p_l - n_l)
\end{aligned} \tag{8.17}$$

#### 8.4.6 Hydrogen-Like Orbitals

$$\Psi(\alpha, \mathbf{r}) = \exp \left[ -\frac{1}{2} \alpha \sum_{i=1}^N r_i \right] \tag{8.18}$$

where the derivative with respect to coordinate  $r_k$  is

$$\nabla_k \ln \Psi(\alpha) = -\alpha \tag{8.19}$$

and the second derivative is

$$\nabla_k^2 \ln \Psi(\alpha) = 0 \tag{8.20}$$

The gradients for those derivatives are

$$\partial_\alpha \nabla_k \ln \Psi(\alpha) = -1 \tag{8.21}$$

and

$$\partial_\alpha \nabla_k^2 \ln \Psi(\alpha) = 0 \tag{8.22}$$

respectively.

Author

Figure 9.1: Caption

Optimization is a wide term..

## 9.1 Minimization Algorithms

Suppose we have a very simple model trying to fit a straight line to data points. In that case, we could manually vary the coefficients and find a line that fits the points quite good. However, when the model gets more complicated, this can be a time consuming activity. Would it not be good if the program could do this for us?

In fact, there exist plenty of methods capable of doing this. Some of them rely on the gradients only, and are therefore called gradient methods. Other need both the gradient and the Hessian matrix, and find the minimum based on both the slope and the curvature of the cost function. For our purpose, gradients methods have provided good results over decades, and there is no need for more complicated algorithms. The standard gradient descent method will be discussed firstly, before we move to its stochastic brother. Momentum will be added for both methods. Finally, we examine the ADAM optimizer, which is stochastic by nature and is equipped with momentum by default.

### 9.1.1 Gradient Descent

Perhaps the simplest and most intuitive method for finding the minimum is the gradient descent method (GD), which reads

$$\alpha_i^{\text{new}} = \alpha_i - \eta \cdot \frac{\partial Q(\alpha_i)}{\partial \alpha_i} \quad (9.1)$$

where  $\alpha_i^{\text{new}}$  is the updated weight  $\alpha$  and  $\eta$  is the learning rate. The idea is to find the steepest slope of the cost function  $Q(\vec{\alpha})$  with respect to a certain  $\alpha_i$ , and move in the direction which minimizes the cost function. For every step, the cost function is thus minimized, and when the gradient approaches zero the minimum is found. A possible stop criterion is

$$\frac{\partial Q(\alpha_i)}{\partial \alpha_i} < \varepsilon. \quad (9.2)$$

where  $\varepsilon$  is a tolerance.

In cases where the cost function is not strictly increasing or decreasing, we will have both local and global minima. Often, it is hard to say whether we are stuck in a local or global minimum, and this is where the stochasticity enters the game.

### 9.1.2 Stochastic Gradient Descent

For standard gradient descent, we calculate the gradient based on all sampling points, we say that we have one batch.

Instead of calculating the gradient based on all sampling points, we can divide the data into multiple batches and calculate the gradient based on one batch and hope that it is a good approximation of the true gradient. Updating weight  $\alpha_i$  based on batch  $j$  thus yields

$$\alpha_i^{\text{new}} = \alpha_i - \eta \cdot \frac{\partial Q_j(\alpha_i)}{\partial \alpha_i} \quad (9.3)$$

and a run through all batches is called an *epoch*.

The reader might ask herself why this helps us, will we not just get a bad gradient approximation? The answer is that the stochasticity adds some coincidence to the system, which makes it less likely to be stuck in local minima. Additionally, it might speed-up the training session.

### 9.1.3 ADAM

ADAM is a first-order stochastic optimization method which is widely used in machine learning. It was discovered by D.P. Kingma and J. Ba, and published in a 2014 paper. The article has already more than 20000 citations! [19] So what makes this method so great?

The main reason why it is so popular might be that it is straight-forward to implement, in the same time as it is efficient and capable of handle a large number of parameters. Additionally, the method has built-in momentum which makes it less likely to be stuck in a local minimum, more about that later.

The algorithm goes as following

---

**Algorithm 1:** The ADAM algorithm

---

```

Data: this text

        go to next section;
        current section becomes this one;
    else
        go back to the beginning of current section;
    end
end

```

---

### 9.1.4 Adding momentum

We have already mentioned momentum, but what is it and why do we use it?

If we go back to an introductory mechanics course, you might remember that momentum is a quantity that maintains the motion of a body. Imagine a ball that rolls down a steep hill, but then there is a local minimum that it needs to escape to keep rolling. Because of its momentum, it will probably be able to escape.

Exactly the same idea lies behind the momentum used in optimization algorithms; the momentum will try to maintain the motion towards the global minimum, which makes the system less likely to be stuck in a local minimum. See figure .. for illustration.

Momentum can be added to most optimization algorithms, also gradient descent and stochastic gradient descent. The way we do it is to ...

$$\mathbf{v} = \gamma \mathbf{v} + \eta \nabla E \quad (9.4)$$

## 9.2 Random number generators

Mersenne Twister needs to be mentioned here

# Chapter 10

## Scientific Programming

Great quote.

---

Author

Figure 10.1: Caption

Since this thesis is much about writing code, it is natural including a few words about it.

The computer's language itself is binary, and is the lowest level. To translate commands to this language, we need a "translator", which is a language that fills the gap between the binary language and human commands. This language is categorized in levels based on how similar they are to the binary language. Low-level languages are similar to the binary language, which means fast but complicated. High-level languages are easy to work with, but are not as fast as low-level languages. Might mention grammar etc

One can either do *procedural programming* or *object oriented programming*. The former means that the code is written in the same order as the program flow goes, while one in the latter defines objects.

## 10.1 Object Orientated Programming

In the everyday life, we are surrounded by objects all the time which we can place in different categories. For instance, a *cat* is an object with a name, race, age and so on, and can be placed in the class *animals*. In object oriented programming, the class could be implemented as

```
class Animal:
    def __init__(self, animal, name, race, age):
        self.animal = animal
        self.name = name
        self.race = race
        self.age = age

    def __call__(self):
        return "%s is a %s that's %d years old and of the race %s"%(self.name, self.animal,
            ↪ self.age, self.race)
```

where...

The next step is to define an object, which in our case is the cat with name "Schrodinger":

```
Alma = Animal("cat", "Schroedeger", "Ragdoll", 4)
print(Alma())
```

This implies that "Schrodinger" is a cat of race "Ragdoll" and of age 4. When calling this class from "Schrodinger", the class returns

```
$python3 simple_class.py
>>> Schrodinger is a cat that's 4 years old and of the race Ragdoll
```

You might wonder how this is related to scientific programming. The answer is that it is often convenient to define various parts of the code as objects to increase the liability and maximize reuse of code. For example, we use various Hamiltonians, where each can be defined as a subclass of the Hamiltonian superclass.

The code above is written in Python, but the exact task could be performed in C++.  
INCLUDE C++ IMPLEMENTATION

As one can see,

In C++ one needs to define constructors and destructors. All variables used inside the functions are defines in the constructor, while they are removed in the destructor to free up memory. In Python, the constructors are called `__init__` by default, and memory is handled automatically.

### 10.1.1 Inheritance

This is also called parent and child, respectively.

Parent and child Polymorphy: Child inherit from the parents. Virtual functions to achieve runtime polymorphism Should define virtual destructor as well

1. Single inheritance
2. Multiple inheritances

Python and C++ support multiple inheritances. Multilevel inheritance: Got child and grand child. Hierarchical inheritance: Parent got several children. <https://www.geeksforgeeks.org/inheritance-in-python/>

### 10.1.2 Pointers

Sometimes we do not want to send the object itself, but either its address, such that..

### 10.1.3 Virtual Functions

Often one wants to define a template of objects... where the super class defines which functions its objects should have. In C++, this can be achieved by virtual functions, functions with arguments specified but task undefined. Those functions are overwritten by the corresponding functions in the object (hence virtual),

### 10.1.4 Data types

To not lose precision, it is important to choose the correct data type. As a thumb rule, a large integer should be declared as a `long int` (or just a `long`), and an extremely large float should be declared as a `long double`. However, normally it is sufficient to declare integers as `ints` and floats as `doubles`.

Some variables should always be non-negative, such as counters and variables that gives the number of something. In those situations, the prefix `unsigned` is useful because it does two things: 1. ensures that a negative number is never assigned to the variable, 2. increases the range in positive direction. In for-loops, the control variable will usually be declared as `unsigned int`.

When using a library some variable types are already set, for instance the length of a standard vector is always given as an `unsigned long`. In those cases, it is most appropriate to continue using that type.

When we tell the pros, we should also tell the cons. With `unsigned` types there is always a risk for underflow, which means that the number explode if it ...

As an additional note, we often want to ensure that a variable is not changed inside a function. To prevent this, the arguments can be passed with the feature `const`, which raises an error if the respective variable is tried changed.

#### 10.1.4.1 Data types in Eigen

The open source template library for linear algebra, Eigen, will be used throughout the coding, and it comes with arrays of various properties. The most relevant ones are `VectorXi`, which has dynamic length and `int` data type and `VectorXd`, which has dynamic length and `double` data type. The Matrix class has equivalent objects.

In cases where we have *a priori* knowledge of the array size, we can replace the `X` with the actual size. A fixed  $3 \times 3$  matrix of type `double` can for example be declared as `Matrix3d`. According to the Eigen documentation, using fixed size is *"...hugely beneficial to performance"*. [https://eigen.tuxfamily.org/dox/group\\_\\_TutorialMatrixClass.html](https://eigen.tuxfamily.org/dox/group__TutorialMatrixClass.html).

# Chapter 11

## Implementation

There are only two hard things  
in Computer Science: cache  
invalidation and naming things.

---

Phil Karlton, [25]

Figure 11.1: Caption

For many projects, planning is half the job, and so is true for a good VMC implementation. In fact, the program was restructured three times before we landed on this final version. It is based on Morten Ledum's VMC framework found at [20], which was meant as an example implementation in the course *FYS4411 - Computational Physics II: Quantum Mechanical Systems*.

For all matrix and array operations, the **Eigen** library was used. All source code can be found at [23].

The code was developed with three main goals. It should be

- readable,

- fast,
- flexible.

How we work to achieve the goals will be illustrated by code mainly picked from the `WaveFunction` class, which is the heart of the code.

## 11.1 Readability

To maximize the readability, we developed a highly object oriented code based on the theory in chapter (10). For instance, each wave function element was treated as an object, with the properties `updateArrays`, `setArrays`, `resetArrays`, `initializeArrays`, `updateParameters`, `evaluateRatio`, `computeGradient`, `computeLaplacian` and `computeParameterGradient`. To ensure that all wave function elements have all the necessary properties, the super class `WaveFunctions` is equipped with the corresponding virtual functions

Listing 11.1: `wavefunction.h`

```
#pragma once
#include <Eigen/Dense>
#include <iostream>

class WaveFunction {
public:
    WaveFunction(class System *system);
    virtual void    updateArrays    (Eigen::VectorXd positions, int pRand) = 0;
    virtual void    setArrays      () = 0;
    virtual void    resetArrays    () = 0;
    virtual void    initializeArrays(Eigen::VectorXd positions) = 0;
    virtual void    updateParameters(Eigen::MatrixXd parameters, int elementNumber) = 0;

    virtual double  evaluateRatio  () = 0;
    virtual double  computeGradient(int k) = 0;
    virtual double  computeLaplacian() = 0;

    virtual Eigen::VectorXd computeParameterGradient() = 0;

    virtual ~WaveFunction() = 0;

protected:
    int    m_numberOfParticles          = 0;
    int    m_numberOfDimensions         = 0;
    int    m_numberOfFreeDimensions     = 0;
    int    m_maxNumberOfParametersPerElement = 0;
    class System* m_system = nullptr;
};
```

which serves as a template for all the sub classes (wave function elements). As you might notice, we use the **lowerCamelCase** naming convention for function and variable names, which means that each word begins with a capital letter except the initial word. For classes, we use the **UpperCamelCase** to distinguish from function names. This is known to be easy to read, and apart from for example the popular **snake\_case**, we do not need delimiters between the words, which saves some space. After the naming convention is decided, we are still responsible for giving reasonable names, which is not always an easy task, as Phil Karlton points out. When one sees the name, one should know exactly what the variable/function/class is or does. More about naming conventions can be read at [22].

## 11.2 Efficiency

The efficiency is mostly based on recursive computations, such that we do not need to calculate everything over again when it is enough to calculate the fraction between the old the new number. This is highly relevant when it comes to the Slater determinant, but we also do this for other wave function elements.

First of all, we need to initialize all position dependent arrays. Some of these are initialized once, and then updated for the rest of the run based on their earlier value. `initializeArrays` does all the magic here.

Every wave function element is equipped with a function, `updateArrays`, where all relevant arrays are updated immediately after a particle is moved. In this way we ensure that nothing is calculated twice inside any element. Those functions are by far the most expensive to calculate, but it is also easier to streamline a really expensive function than several quite expensive ones.

Inside `updateArrays`, we first need to update the old variables, typically named like `m_positionsOld` or so. This is generally done by calling the function `setArrays`, which ensures that all the old variables are correct. We need to store the old variables in case a move is rejected and we need to go back to the old positions. Thereafter, we can update all the variables. The most basic example is the Gaussian function, where we basically only need to update the position and the probability ratio.

Listing 11.2: from `gaussian.cpp`

```
void Gaussian::updateArrays(Eigen::VectorXd positions, int changedCoord) {
    setArrays();
    m_positions = positions;
    updateProbabilityRatio(changedCoord);
}

void Gaussian::setArrays() {
    m_positionsOld = m_positions;
    m_probabilityRatioOld = m_probabilityRatio;
}

void Gaussian::updateProbabilityRatio(int changedCoord) {
    m_probabilityRatio = exp(m_omega * m_alpha * (m_positionsOld(changedCoord) * \
    m_positionsOld(changedCoord) - m_positions(changedCoord) * m_positions(changedCoord)));
}
```

Similarly to the function `setArrays`, there is also a function `resetArrays`, which is called then a move is rejected. It works the exact opposite way, looking like

Listing 11.3: from `gaussian.cpp`

```
void Gaussian::resetArrays() {
    m_positions = m_positionsOld;
    m_probabilityRatio = m_probabilityRatioOld;
}
```

There are also a few arrays that are used inside multiple wave function elements, such as the distance matrix and the radial distance vector. They might also be used in the Hamiltonian. To ensure that they are not calculated more than necessary, we define them globally together with a respective Boolean which tells us whether or not the array is updated at the present cycle.

Listing 11.4: from `system.cpp`

```
NEED TO ADD EXACT IMPLEMENTATION
```

For profiling, we used `callgrind` with `kcachegrind` visualization, which are great tools when we want to find out which functions that steal CPU time.

## 11.3 Flexibility

Unlike many other VMC codes, our code was developed flexible with respect to the wave functions. This means that one can combine various wave function elements, where each element is implemented separately. For instance, the Gaussian function, the Slater determinant and the Padé-Jastrow factor were implemented separately, but they all can easily be combined. The way one does this in practice, is to append multiple wave function elements to the vector `WaveFunctionElements` in `main`. One can combine the Gaussian with the Padé-Jastrow factor and the Slater determinant in the following way

Listing 11.5: from `main.cpp`

```
System* system = new System();
std::vector<class WaveFunction*> WaveFunctionElements;
WaveFunctionElements.push_back(new class Gaussian(system));
WaveFunctionElements.push_back(new class PadeJastrow(system));
WaveFunctionElements.push_back(new class SlaterDeterminant(system));
system->setWaveFunctionElements(WaveFunctionElements);
```

The big advantage of this implementation technique is that we do not need to hard code every possible combination of wave function elements, which reduces the number of code lines significantly. This also eases the operation of adding new elements, since we only need to calculate the derivatives of the particular element (do not need to worry about cross terms). Exactly how this is done can be read in chapter 8. The con is that the program will be slightly slower, since even canceling cross terms are calculated.

### 11.3.1 Energy calculation

The way we calculate the total kinetic energy then is based on the theory presented in chapter 8, where we explain that

$$T = -\frac{1}{2} \frac{1}{\Psi_T} \nabla_k^2 \Psi_T = -\frac{1}{2} \left[ \sum_{i=1}^p \nabla_k^2 \ln \phi_i + \left( \sum_{i=1}^p \nabla_k \ln \phi_i \right)^2 \right]. \quad (11.1)$$

The corresponding implementation thus reads

Listing 11.6: from `system.cpp`

```
double System::getKineticEnergy() {
    double kineticEnergy = 0;
    for(auto& i : m_waveFunctionElements) {
        kineticEnergy += i->computeLaplacian();
    }
    for(int k = 0; k < m_numberOfFreeDimensions; k++) {
        double nablaLnPsi = 0;
        for(auto& i : m_waveFunctionElements) {
            nablaLnPsi += i->computeGradient(k);
        }
        kineticEnergy += nablaLnPsi * nablaLnPsi;
    }
    return - 0.5 * kineticEnergy;
}
```

### 11.3.2 Probability ratio calculation

In the same chapter we state the obvious fact that

$$\frac{\Psi_T^{\text{new}}}{\Psi_T^{\text{old}}} = \prod_{i=1}^p \frac{\phi_i^{\text{new}}}{\phi_i^{\text{old}}},$$

which can easily be implemented as

Listing 11.7: from `system.cpp`

```
double System::evaluateWaveFunctionRatio() {
    double ratio = 1;
    for(auto& i : m_waveFunctionElements) {
        ratio *= i->evaluateRatio();
    }
    return ratio;
}
```

### 11.3.3 Parameters

Another consequence of this flexible implementation is that we need to treat all parameters in the same way to make everything general. To do this, we create a global matrix of dimensions  $n \times m$  where  $n$  is the number of wave function elements and  $m$  is the maximum number of parameters in a wave function element. Thus each element has its own row in the matrix, and one can easily track down a specific parameter.

For the parameter update, each element needs to provide an array of length  $m$  containing its respective parameter gradients. This array is calculated in the function `computeParameterGradient` for each element, and they are all collected in the function `getAllInstantGradients`:

Listing 11.8: from `system.cpp`

```
Eigen::MatrixXd System::getAllInstantGradients() {
    Eigen::MatrixXd gradients = Eigen::MatrixXd::Zero(m_numberOfWaveFunctionElements, \
        m_maxNumberOfParametersPerElement);
    for(int i = 0; i < m_numberOfWaveFunctionElements; i++) {
        gradients.row(i) = m_waveFunctionElements[i]->computeParameterGradient();
    }
    return gradients;
}
```

We need to stress that those are the instant gradients calculated every time a particle is moved. Exactly how the parameters are updated depends on an average of these, described in chapter 8.

Immediately after the parameters are updated, the new parameters need to be sent into the wave function elements. This is done through the functions `updateParameters`, which update all the parameters and weights in the elements. In addition, the function has the responsibility to order the elements such that none gets the same number.

## 11.4 Structure

How the classes are communicating is no easy task to explain, most classes are calling other classes, there is no tidy way to visualize the actual code flow. However, a simplified structure chart can still be informative, and in figure (??) the most important calls between the different classes are pointed out. We decided to leave out `main.cpp` since all it does is to set the different classes.

This is the main aim of the flow, but the actual flow does also depend on system. For instance, when using importance sampling, we will have an additional call between `WaveFunctions` and `Metropolis` due to calculations of the quantum force.

- |                                   |  |
|-----------------------------------|--|
| 1 - Set random initial weights    | 8 - Get basis used in Slater determinant |
| 2 - Set weights in wave functions | 9 - Sample                               |
| 3 - Set random initial positions  | 10 - Compute local energy                |
| 4 - Propose random move           | 11 - Calculate instant gradients         |
| 5 - Evaluate wave functions       | 12 - Calculate energy derivatives        |
| 6 - Update positions              | 13 - Calculate average gradients         |
| 7 - Accept or reject step         |  |

Figure 11.2: Structure chart of the implemented code, presenting super classes as tiles. The most important intra-class calls are represented with lines pointing from the sender class towards the receiver class.

## 11.5 Foundation

The foundation of the code are all the super classes, nine in the number. They all have multiple sub classes, and the reader needs to specify which sub class to be used. The exception is the `WaveFunctions` class, as described above, where multiple sub classes can be used. Below, the role of all the super classes will be discussed briefly and the difference between various sub classes will be explained.

### 11.5.1 Super classes

#### 11.5.1.1 The Basis class

In this class, one needs to choose which basis set that should be used in the Slater determinant. There are three required functions:

- `numberOfOrbitals()` gives the number of orbitals given the number of particles and dimensions. This is used in the Slater determinant.
- `evaluate(double x, int n)` gives the the value of element `n` for a given `x`.
- `evaluateDerivative(double x, int n)` gives the derivative of element `n` with respect to `x` for a given `x`.

Possible sub classes choices are `Hermite` and `HydrogenLike`, where the former is well-suited for quantum dots and the latter is used in atomic structure calculations.

#### 11.5.1.2 The Hamiltonians class

In this class, one needs to specify the Hamiltonian of the system. The only required function is `computeLocalEnergy()`, which returns the local energy. One can choose between the Hamiltonians `AtomicNucleus` and `HarmonicOscillator`, where the first one sets up an external potential like the one we find in an atom, and takes the atomic number `Z` as an argument. The second one sets up a harmonic oscillator potential, and actually the only thing that distinguish the who classes is the external energy calculation.

#### 11.5.1.3 The InitialStates class

In one way or another we need to initialize the particle positions, but how we want to do this depends on the situation. The implemented methods are randomly initialized positions drawn from a uniform or normal distribution, `RandomUniform` and `RandomNormal` respectively. They consist of the function `setupInitialState()`.

#### 11.5.1.4 The InitialWeights class

In the same manner as the `InitialStates` class, we can initialize the weights in various ways. One way is to set all the weights to the same initial value, represented by the sub class `Constant`. It takes an argument `factor` which gives the initial value of all weights.

A second choice is random initial weights, where the class `Randomize` initializes the weights based on a uniform distribution. Also this class takes the `factor` argument, which defines the interval. By default, the interval is `[-1,1]`, which corresponds to `factor=1`.

#### 11.5.1.5 The Metropolis class

This class is the true sampling class, where the magic sampling is done. Three sampling methods are implemented:

- `BruteForce` is the standard Metropolis sampling, where a particle is moved in a totally random direction and the move is accepted if the new probability is high enough.
- `ImportanceSampling` is a more advanced version of the Metropolis algorithm, where the particle is moved in the same direction as the quantum force.
- `GibbsSampling` is not directly related to the Metropolis algorithm, it is a simple method which is widely used in Boltzmann machines.

The sub classes need to have the function `acceptMove()`, where the particle is moved and the the move is either accepted or rejected. To get the new positions, one need to call `updatePositions()`. which is member of the super class.

### 11.5.1.6 The Optimization class

The next class is the `Optimization` class, where the weight update is performed in the function `updateWeights()`. Also the instant gradients (the gradient for each step) is calculated here, in the function `getAllInstantGradients()`.

Two gradient based stochastic methods are implemented: `StochasticGradientDescent` and `ADAM`, with descriptive names. They both takes an argument `gamma` which is the prefactor in front of the momentum. The reader can consult chapter (9) for details on how the optimization methods work.

### 11.5.1.7 The Plotter class

Not sure if I will keep this as a class

### 11.5.1.8 The RNG class

The random number generator (RNG) was implemented as a class to ease the switch between different RNGs. Each subclass need to contain the following functions:

- `nextInt(int upperLimit)` returns the next number in the RNG sequence as an integer between 0 and `upperLimit`.
- `nextDouble()` returns the next number in the RNG sequence as a double between 0 and 1.
- `nextGaussian(double mean, double standardDeviation)` returns the next number in the RNG sequence, regenerated by a normal distribution with mean value `mean` and standard deviation `standardDeviation`.

The two available RNGs are the Mersenne Twister number generator, `MersenneTwister` and... . For the theory behind thoe methods, see section (9.2).

### 11.5.1.9 The WaveFunctions class

Last, but not least, the `WaveFunctions` class contains all the wave function related computations. We have already mentioned it, but all the details are still to be stressed.

The required functions in the wave function elements are

- `updateArrays(Eigen::VectorXd positions, int pRand)` which update position dependent arrays recursively with respect to the new positions, `positions` and the changed position index `pRand`.
- `resetArrays()` set the arrays back to the old values when a move is rejected.
- `initializeArrays(Eigen::VectorXd positions)` initialize all arrays at the beginning. This is the only moment when the arrays cannot be updated recursively.
- `updateParameters(Eigen::MatrixXd parameters, int elementNumber)` updates the weights. All weights of the system are stored in the parent matrix `parameters`, while each wave function element has child weight matrices and arrays which are mapped from the parent. They are all updated in this function. `elementNumber` is the number of the element, and is unique for all the wave function elements.

- `evaluateRatio()` returns the ratio between the new and the old probability,  $|\Psi_T(\mathbf{r}_{\text{new}})|^2/|\Psi_T(\mathbf{r}_{\text{old}})|^2$
- `computeFirstDerivative(int k)` returns the first derivative of the wave function element with respect to the position index  $\mathbf{k}$ .
- `computeSecondDerivative()` returns the second derivative of the wave function element with respect to all position indices.
- `computeFirstEnergyDerivative(int k)` returns the derivative of the position  $\mathbf{k}$  first derivative of the wave function element with respect to all the weights,  $\partial/\partial\alpha_i \nabla_k \ln(\psi)$ . The outcome is an array.
- `computeSecondEnergyDerivative()` returns the derivative of the position second derivative of the wave function element with respect to all the weights,  $\sum_k \partial/\partial\alpha_i \nabla_k^2 \ln(\psi)$ . The outcome is an array.

The wave function elements implemented are

- `Gaussian` is the simple Gaussian function.
- `PadeJastrow` is the Padé-Jastrow factor.
- `SlaterDeterminant` is the Slater determinant.
- `MLGaussian` is the Gaussian part derived from the Boltzmann machines.
- `NQSJastrow` is the product part derived from the Boltzmann machines.

New wave function elements can easily be implemented, all one needs to do is to calculate all the derivatives and specify how to update the position dependent arrays recursively.

### 11.5.2 How to set sub classes?

We have now described all the available super classes and sub classes, but how do we set them? As hinted in the beginning of the chapter, the entire system should be specified in `main.cpp`. For example, a harmonic oscillator Hamiltonian can be set by

```
system->setHamiltonian(new HarmonicOscillator(system));
```

which is calling the function `setHamiltonian` in the class `System`. This function sets the official Hamiltonian object to `HarmonicOscillator`, such that every time we call the super class `Hamiltonian`, we are forwarded to `HarmonicOscillator`. The `System` class is basically filled with functions that set objects and scalars. To make those objects and scalars available in other classes, the `System` header is equipped with get-functions. For instance, there exist a function

```
class Hamiltonian* getHamiltonian() { return m_hamiltonian; }
```

which returns the correct Hamiltonian sub class. In the other classes where the `System` objects appears as `m_system`, the local energy can be found by

```
double localEnergy = m_system->getHamiltonian->computeLocalEnergy();
```

Similar functions exist for other essential objects, arrays and scalar.

## 11.6 Graphical User Interface (GUI)

# Chapter 12

## Results

Great quote.

---

Author

Figure 12.1: One-body density plots for 12 particles in a harmonic oscillator well. The four graphs correspond to four different oscillator strengths, where the weakest oscillator gives the broadest density distribution. It's quite artistic, isn't it?

After all, this is a physics thesis and the physical results is what is interesting. The results are really the heart of this thesis and where most the effort is put...

We will first highlight some selected results with no repulsive interaction for validation purposes, and then move on to the more realistic case where we look at a larger number of particles for various oscillator strengths and various wave functions structures in two and three dimensions.

## 12.1 Computational cost

One of the major problems of quantum many-body simulations is the computational cost, which explodes as the system size increases. In figure (??) the CPU-time is plotted as a function of full orbitals.

Figure 12.2: CPU-time as a function of full orbitals for two and three dimensions. The solid line is RBM, while the dashed line is VMC.

A quantum many-body simulation is an actual experiment, since the applied theory agrees perfectly with the experiments. In that manner, one can use computer experiments to predict things that is not investigated in real life. Similarly to experiments in a lab, computer experiments are also dependent on external factors, especially when it comes to the CPU-time, and therefore it is important to do such measurements multiple times to find an accurate average time. The CPU-times above are the average from at least four independent runs for each number of orbitals. All the runs were performed on the Abel computational cluster, which is equipped with Supermicro X9DRT compute nodes with dual Intel E5-2670 CPUs running at 2.6 GHz. Different hardware might cause different CPU-times, but the CPU-time ratios (the exponential factor) should be the same.

To find the increasing power, we try to fit a function on the form

$$f(x) = ax^b \quad (12.1)$$

to the curve, where  $x$  is the number of orbitals while  $a$  and  $b$  are parameters to find. From the limited number of points, we have found the parameters and presented them in table (12.1).

Table 12.1

	2D		3D	
	$a$	$b$	$a$	$b$
RBM	-	-	-	-
RBM+HF	-	-	-	-
RBM+PJ	-	-	-	-
VMC	0.23	3.52	0.23	4.76

## 12.2 Energy convergence

Another interesting comparison is the convergence of the different methods...

(a) 2D, 2P,  $\omega = 1$

(b) 3D, 2P,  $\omega = 1/2$

Figure 12.3

## 12.3 No repulsive interaction

We start with the non-interacting case in order to validate the implemented code. In this case we both know the exact energies and the exact one-body densities for an array of systems, and can therefore test the flexibility of the code.

### 12.3.1 Ground state energy

#### 12.3.1.1 Quantum dots

We will start studying systems with no interaction between particles. The number of closed-shell particles are given by equation (3.5) and the exact energies are found from formula (3.4). The first 5 closed-shell energies for  $\omega = 0.5$  and  $\omega = 1.0$  are presented in table (12.2).

Table 12.2: Energy of  $N$  non-interacting electrons trapped in a harmonic oscillator of frequency  $\omega = 0.5$  and  $\omega = 1.0$ .  $E_{\text{RBM}}$  is a single Slater determinant with a plain Boltzmann machine baked in, while  $E_{\text{VMC}}$  is standard variational Monte-Carlo.

	$\omega$	0.5			1.0		
	$N$	$E_{\text{RBM}}$	$E_{\text{VMC}}$	$E_{\text{exact}}$	$E_{\text{RBM}}$	$E_{\text{VMC}}$	$E_{\text{exact}}$
2D	2	1.00045(5)	1.0	1	2.00098(5)	2.0	2
	6	5.009(2)	5.0	5	10.010(1)	10.0	10
	12	-	14.0	14	-	28.0	28
	20	-	30.0	30	-	60.0	60
	30	-	55.0	55	-	110.0	110
3D	2	1.5050(3)	1.5	1.5	3.0063(2)	3.0	3
	8	-	9.0	9	-	18.0	18
	20	-	30.0	30	-	60.0	60
	40	-	75.0	75	-	150.0	150
	70	-	157.5	157.5	-	315.0	315

We observe that the NQS wave function is able to reproduce the exact energy for most of the cases, but when the number of particles get large, the statistical error gets significant.

#### 12.3.1.2 Atoms

In the next we will study atoms when the Coulomb interaction is ignored. For those cases, we know the exact answers, given by the Bohr formula presented in equation (3.8).

Table 12.3: The table shows the computed energies of non-interacting atoms with the analytical solution to the right.  $E_{\text{RBM}}$  is a single Slater determinant with a plain Boltzmann machine baked in, while  $E_{\text{VMC}}$  is standard variational Monte-Carlo.

Atom	$N$	$E_{\text{RBM}}$	$E_{\text{VMC}}$	$E_{\text{exact}}$
H	1	-	-0.5	-0.5
He	2	-	-4.0	-4
Be	4	-	-	-20
Ne	10	-	-	-200

### 12.3.2 One-body density

The one-body densities

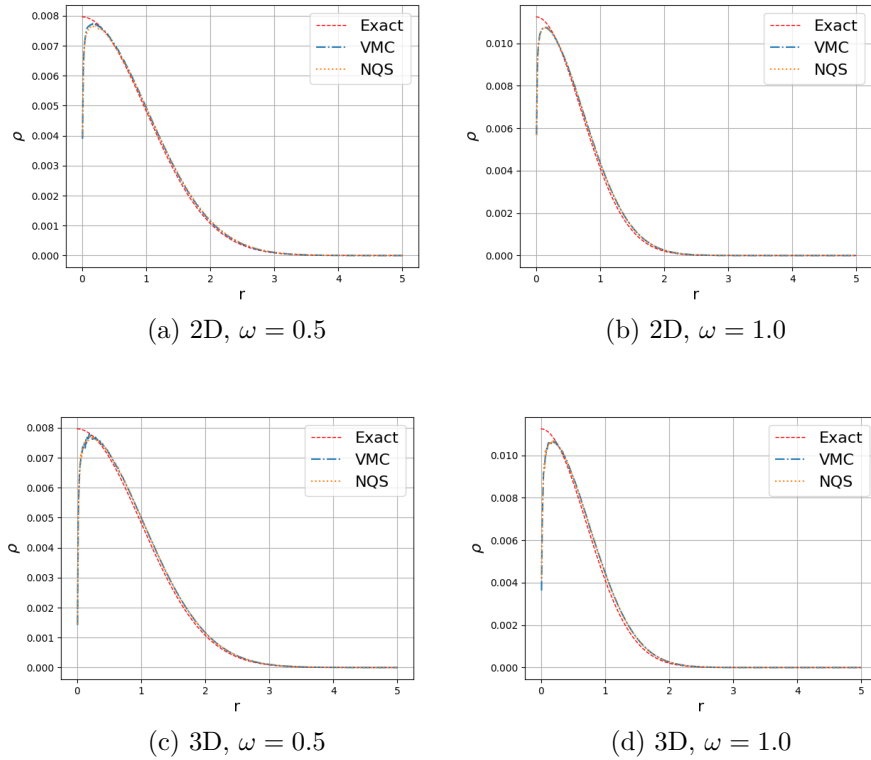

Figure 12.4: One-body densities of two non-interacting electrons in two dimensions figure (a) and (b) and three dimensions

## 12.4 With repulsive interaction

### 12.4.1 Ground state energy

#### 12.4.1.1 Two dimensions

Table 12.4: This table presents the energies of  $N$  electrons trapped in a two-dimensional oscillator well with frequency  $\omega$ .  $E_{\text{RBM}}$  is plain restricted Boltzmann machine (RBM) with Slater determinant,  $E_{\text{RBM+PJ}}$  is RBM with Padé-Jastrow factor (PJ), and  $E_{\text{VMC}}$  is standard variational Monte-Carlo. The exact energies are calculated analytically by M.Taut, see [7]. The reference is to J. Høgberget's diffusion Monte-Carlo (DMC) calculations [15].

$N$	$\omega$	$E_{\text{RBM+PJ}}$	$E_{\text{RBM}}$	$E_{\text{RBM+HF}}$	$E_{\text{PRBM}}$	$E_{\text{DRBM}}$	$E_{\text{VMC}}$	$E_{\text{HF}}$	$E_{\text{ref}}$
2	0.1	0.44130(5)	0.4728(1)	-	-	-	0.44128(1)	0.525635	0.44079(1)
	1/6	0.66715(6)	0.7036(1)	-	-	-	0.66710(1)	0.768675	0.6 <sup>1</sup>
	0.28	1.02185(1)	1.0705(2)	-	-	-	1.02190(1)	1.141712	1.02164(1)
	0.5	1.65957(1)	1.7231(2)	-	-	-	1.65972(1)	1.799742	1.65977(1)
	1.0	3.00002(2)	3.0822(2)	-	-	-	2.99999(1)	3.161908	3.0 <sup>1</sup>
6	0.1	3.5868(6)	3.7475(2)	-	-	-	3.5698(1)	3.852381	3.55385(5)

### 12.4.1.2 Three dimensions

Table 12.5: This table presents the energies of  $N$  electrons trapped in a three-dimensional oscillator well with frequency  $\omega$ .  $E_{\text{RBM}}$  is plain restricted Boltzmann machine (RBM) with Slater determinant,  $E_{\text{RBM+PJ}}$  is RBM with Padé-Jastrow factor (PJ), and  $E_{\text{VMC}}$  is standard variational Monte-Carlo. The exact energies are calculated analytically by M.Taut, see [6]. The reference is to J. Høgberget's diffusion Monte-Carlo (DMC) calculations [15].

	1.0	-	-	-	-	-	1108.950(4)	-	-

Now over to the interesting part: the more realistic case with interaction. We no longer have analytical results, apart from a few semi-analytical energies and wave-functions obtained by M. Taut for the two- and three-dimensional harmonic oscillator. More precisely, he found the energy to be  $E = 3$  for the frequency  $\omega = 1$  and  $E = 2/3$  for the frequency  $\omega = 1/6$  for the two-dimensional case, and  $E = 2$  for the frequency  $\omega = 1/2$  and  $E = 1/2$  for the frequency  $\omega = 1/10$  for the three-dimensional case. [6][7]

For other references, we need to rely on what researchers have found before us. Since diffusion Monte-Carlo (DMC) is known to give very accurate results, we will mainly compare our results to J. Høgberget's DMC calculations. [15] We also run some simulations that we do not have any references for,

To achieve good results, we applied an adaptive step number, which means that the number of steps per iteration was increased for the last iterations. Firstly, this makes the resulting energies more accurate due to better statistics. Secondly, we get less noisy electron density plots by using this technique. All results below were produced using  $2^{20} = 1.048.576$  number of steps per iteration for the initial iterations. Then the number of steps was increased to  $2^{24} = 16.777.216$  when we had 11 iterations left, and for the final iteration we used  $2^{28} = 268.435.456$  steps. The ADAM optimizer was used.

## 12.4.2 One-body densities

### 12.4.2.1 Two dimensions

Figure 12.5: One-body densities of two interacting electrons in two dimensions for various oscillator frequencies produced by standard variational Monte-Carlo (VMC), plain restricted Boltzmann machine (RBM) and restricted Boltzmann machine with Padé-Jastrow factor (RBMPJ). Stochastic gradient descent was used, and after convergence the number of Monte-Carlo cycles was  $MC = 2^{28} = 268.435.456$ .

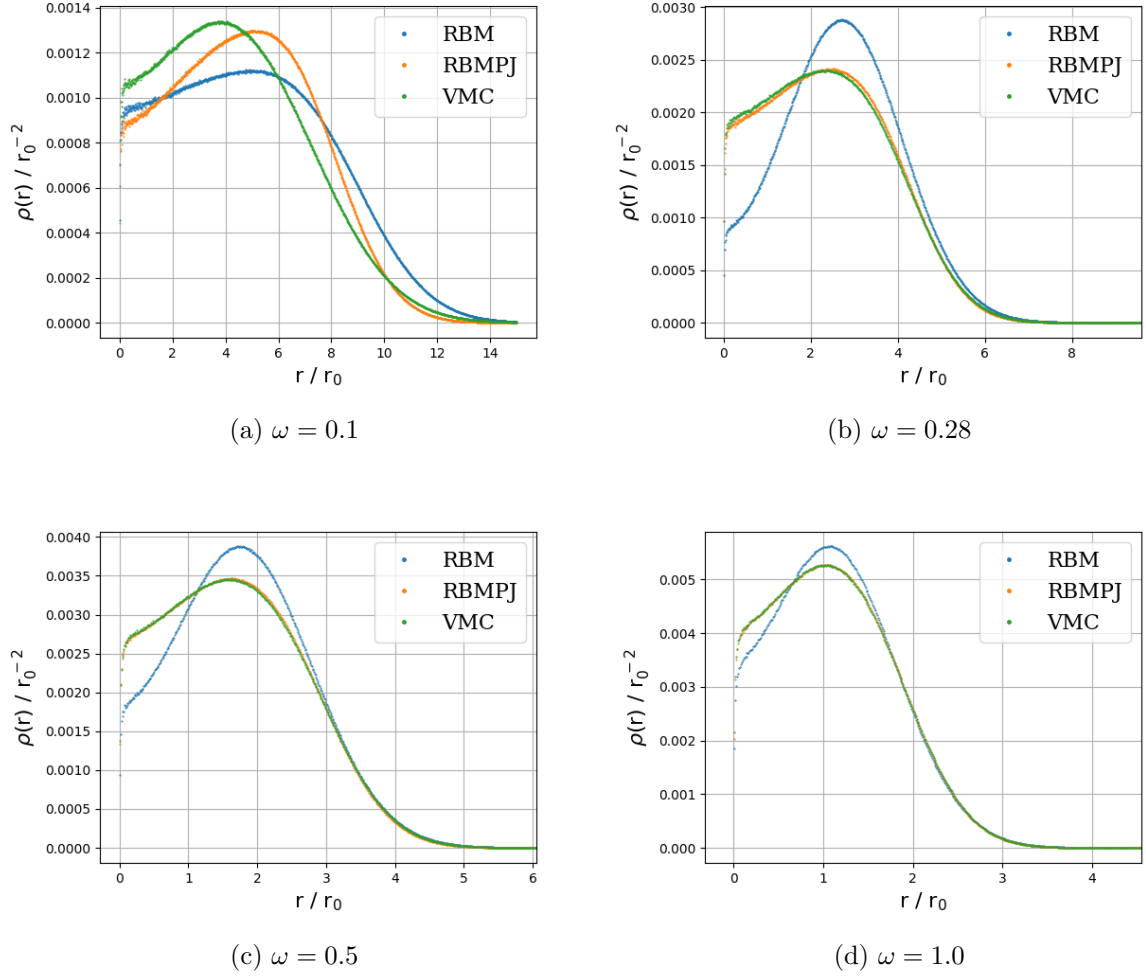

Figure 12.6: One-body densities of six interacting electrons in two dimensions for various oscillator frequencies produced by standard variational Monte-Carlo (VMC), plain restricted Boltzmann machine (RBM) and restricted Boltzmann machine with Padé-Jastrow factor (RBMPJ). Stochastic gradient descent was used, and after convergence the number of Monte-Carlo cycles was  $MC = 2^{28} = 268.435.456$ .

(a)  $\omega = 0.1$ (b)  $\omega = 0.28$ (c)  $\omega = 0.5$ (d)  $\omega = 1.0$ 

Figure 12.7: One-body densities of 12 interacting electrons in two dimensions for various oscillator frequencies produced by standard variational Monte-Carlo (VMC), plain restricted Boltzmann machine (RBM) and restricted Boltzmann machine with Padé-Jastrow factor (RBMPJ). Stochastic gradient descent was used, and after convergence the number of Monte-Carlo cycles was  $MC = 2^{28} = 268.435.456$ .

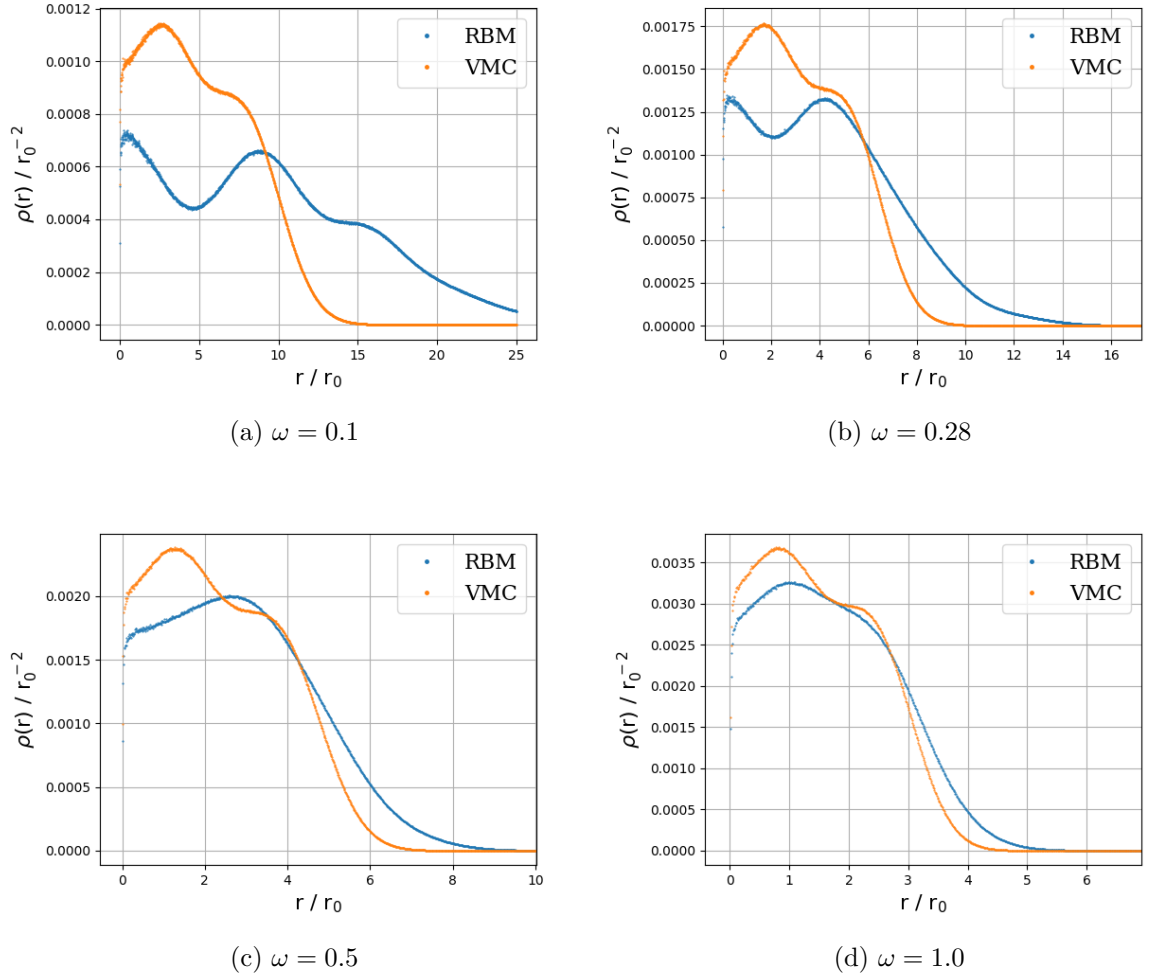

Figure 12.8: One-body densities of 20 interacting electrons in two dimensions for various oscillator frequencies produced by standard variational Monte-Carlo (VMC), plain restricted Boltzmann machine (RBM) and restricted Boltzmann machine with Padé-Jastrow factor (RBMPJ). Stochastic gradient descent was used, and after convergence the number of Monte-Carlo cycles was  $MC = 2^{28} = 268.435.456$ .

(a)  $\omega = 0.1$ (b)  $\omega = 0.28$ (c)  $\omega = 0.5$ (d)  $\omega = 1.0$

Stochastic gradient descent was used, and after convergence the number of Monte-Carlo cycles was  $MC = 2^{28} = 268.435.456$ .

## 12.4.2.2 Three dimensions

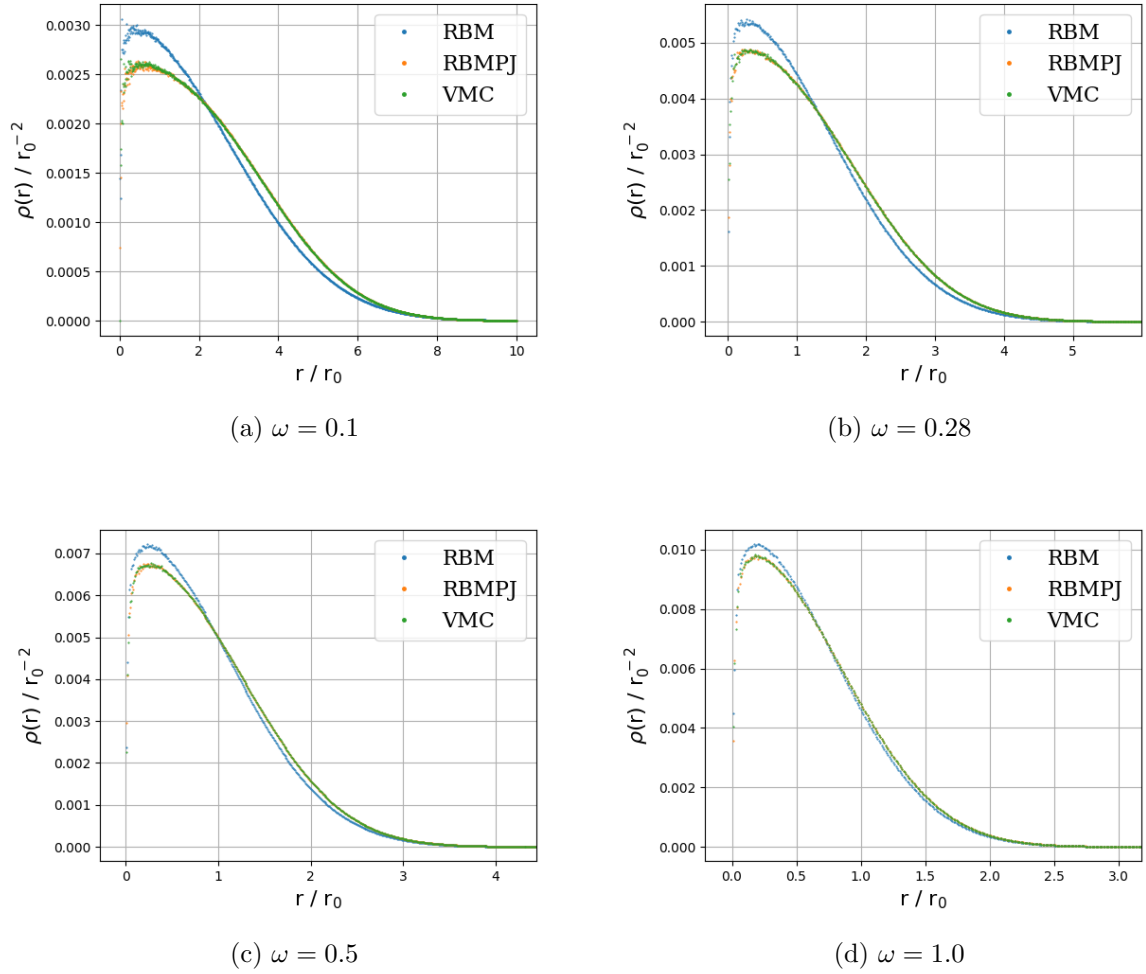

Figure 12.10: One-body densities of two interacting electrons in three dimensions for various oscillator frequencies produced by standard variational Monte-Carlo (VMC), plain restricted Boltzmann machine (RBM) and restricted Boltzmann machine with Padé-Jastrow factor (RBMPJ). Stochastic gradient descent was used, and after convergence the number of Monte-Carlo cycles was  $MC = 2^{28} = 268.435.456$ .

Figure 12.11: One-body densities for eight interacting electrons in three dimensions for various oscillator frequencies produced by standard variational Monte-Carlo (VMC) and plain restricted Boltzmann machine (RBM). Stochastic gradient descent was used, and after convergence the number of Monte-Carlo cycles was  $MC = 2^{28} = 268.435.456$

Figure 12.12: One-body densities of eight interacting electrons in three dimensions for various oscillator frequencies produced by standard variational Monte-Carlo (VMC), plain restricted Boltzmann machine (RBM) and restricted Boltzmann machine with Padé-Jastrow factor (RBMPJ). Stochastic gradient descent was used, and after convergence the number of Monte-Carlo cycles was  $MC = 2^{28} = 268.435.456$ .

### 12.4.3 Two-body density plots

#### 12.4.3.1 Two dimensions

Figure 12.13: Two-body densities for interacting electrons in two dimensions for  $\omega = 0.5$  produced by standard variational Monte-Carlo (VMC), plain restricted Boltzmann machine (RBM) and restricted Boltzmann machine with Padé-Jastrow factor (RBMPJ). ADAM optimizer was used, and after convergence the number of Monte-Carlo cycles was  $MC = 2^{28} = 268.435.456$ .

Figure 12.14: Two-body densities for two interacting electrons in two dimensions for various oscillator frequencies produced by standard variational Monte-Carlo (VMC), plain restricted Boltzmann machine (RBM) and restricted Boltzmann machine with Padé-Jastrow factor (RBMPJ). ADAM optimizer was used, and after convergence the number of Monte-Carlo cycles was  $MC = 2^{28} = 268.435.456$ .

## 12.4.3.2 Three dimensions

Figure 12.15: Two-body densities for 72 interacting electrons in two dimensions for various oscillator frequencies produced by standard variational Monte-Carlo (VMC), plain restricted Boltzmann machine (RBM) and restricted Boltzmann machine with Padé-Jastrow factor (RBMPJ). ADAM optimizer was used, and after convergence the number of Monte-

# Chapter 13

## Conclusion and future work

See if machine learning is able to describe the three-body interaction, with nuclear physics applications.

# Appendix A

## Dirac notation

The Dirac notation, also called bracket notation, was suggested by Paul Dirac in a 1939 paper with the purpose of improving the reading ease. [**dirac1939**]

# Appendix B

## Scaling

### B.1 Harmonic Oscillator - Natural units

The Hamiltonian is in one dimension given by

$$\hat{\mathcal{H}} = -\frac{\hbar^2}{2m} \frac{\partial^2}{\partial x^2} + \frac{1}{2} m \omega^2 x^2 \quad (\text{B.1})$$

which has corresponding wave functions

$$\psi_n(x) = \frac{1}{\sqrt{2^n n!}} \cdot \left( \frac{m\omega}{\pi \hbar} \right)^{1/4} \exp\left(-\frac{m\omega}{2\hbar} x^2\right) H_n\left(\sqrt{\frac{m\omega}{\hbar}} x\right). \quad (\text{B.2})$$

We want to get rid of  $\hbar$  and  $m$  in equation (B.1), and we start with scaling  $H' \equiv H/\hbar$ , such that the Hamiltonian reduces to

$$\hat{\mathcal{H}}' = -\frac{\hbar}{2m} \frac{\partial^2}{\partial x^2} + \frac{1}{2} \frac{m\omega^2}{\hbar} x^2 \quad (\text{B.3})$$

One can now observe that the fraction  $\hbar/m$  comes in both terms, which we can take out by scaling the length  $x' \equiv x \cdot \sqrt{m/\hbar}$ . The final Hamiltonian is

$$\hat{\mathcal{H}} = \frac{1}{2} \frac{\partial^2}{\partial x^2} + \frac{1}{2} \omega^2 x^2 \quad (\text{B.4})$$

which corresponds to setting  $\hbar = m = 1$ . In natural units, one often sets  $\omega = 1$  as well by scaling  $\hat{\mathcal{H}}' = \hat{\mathcal{H}}/\hbar\omega$ , but since we want to keep the  $\omega$ -dependency, we do it slightly different. This means that the exact wave functions for the one-particle-one-dimension case is

$$\psi_n(x) = \exp\left(-\frac{\omega}{2} x^2\right) H_n(\sqrt{\omega} x) \quad (\text{B.5})$$

where we take advantage of the Metropolis algorithm and ignore the normalization constant.

## B.2 Atomic systems - Atomic units

The atomic Hamiltonian in its simplest form is given by

$$\hat{\mathcal{H}} = -\frac{\hbar^2}{2m} \frac{\partial^2}{\partial r^2} - k \frac{Ze^2}{r} + \frac{\hbar^2 l(l+1)}{2mr^2}. \quad (\text{B.6})$$

The first step is to divide all terms by  $\hbar^2/m$ ,

$$\hat{\mathcal{H}} \cdot \frac{m}{\hbar^2} = -\frac{1}{2} \frac{\partial^2}{\partial r^2} + k \frac{m}{\hbar^2} \frac{Ze^2}{r} - \frac{1}{2} \frac{l(l+1)}{r^2} \quad (\text{B.7})$$

and then define  $a \equiv mke^2/\hbar^2$ . If we then divide all terms by  $a^2$ , we can write the Hamiltonian as

$$\hat{\mathcal{H}} \cdot \frac{m}{a^2 \hbar^2} = -\frac{1}{2a^2} \frac{\partial^2}{\partial r^2} + \frac{Z}{ar} - \frac{1}{2a^2} \frac{l(l+1)}{r^2} \quad (\text{B.8})$$

and obtain a dimensionless equation by scaling  $r' = ar$  and  $\hat{\mathcal{H}}' = \hat{\mathcal{H}} \cdot m/a^2 \hbar^2$ . The final Hamiltonian is

$$\hat{\mathcal{H}} = -\frac{1}{2} \frac{\partial^2}{\partial r'^2} - \frac{Z}{r'} + \frac{l(l+1)}{2r'^2}. \quad (\text{B.9})$$

## B.3 Comparison between natural and atomic units

As a summary, we will present how the observable are scaled nicely in a table, and how to convert them back to standard units.

Table B.1: Comparison the natural and atomic units presented above.

Quantity	Symbol	Natural units	Atomic units
Energy	$E$	$1/\hbar$	$\hbar^2/m(ke^2)^2$
Length	$r$	$\sqrt{m/\hbar}$	$m(ke^2)/\hbar^2$
Reduced Planck's constant	$\hbar$	1	1
Elementary charge	$e$	1	$\sqrt{\alpha}$
Coulomb's constant	$k_e$	1	1
Boltzmann's constant	$k_B$	1	1
Electron rest mass	$m_e$	1	$511keV$

By a mix of classical and quantum mechanics, Niels Bohr found the quantized energy levels and radii in an atom to be

$$E_n = -\frac{Z^2(ke^2)^2 m}{2\hbar^2 n^2} \approx -\frac{Z^2}{n^2} 13.6 \text{ eV} \quad (\text{B.10})$$

and

$$r_n = \frac{n^2 \hbar^2}{Zke^2 m} \approx \frac{n^2}{Z} 5.29 \cdot 10^{-11} \text{ m} \quad (\text{B.11})$$

respectively. What we observe, is that the energy in atomic units is scaled with respect to  $2 \cdot E_1$  and  $r_1$ , which means that

$$1 \text{ a.u.} = 2 \cdot 13.6 \text{ eV} \quad \text{and} \quad 1 \text{ a.u.} = 5.29 \cdot 10^{-11} \text{ m} \quad (\text{B.12})$$

# Appendix C

## Associated Laguerre Polynomials

Associated Laguerre polynomials  $L_{q-p}^p(x)$  are solutions of the linear differential equation

$$xy'' + (p+1-x)y' + qy = 0, \quad (\text{C.1})$$

which can be represented by the Rodriguez formula

$$L_{q-p}^p(x) = (-1)^p \left( \frac{d}{dx} \right)^p L_q(x) \quad (\text{C.2})$$

where  $L_q(x)$  are the Laguerre polynomials

$$L_q(x) = e^x \left( \frac{d}{dx} \right)^q e^{-x} x^q. \quad (\text{C.3})$$

### C.1 Recursive relation between polynomials

If one knows the elements  $L_{n-1}^k(x)$  and  $L_n^k(x)$ , the next element can be calculated by

$$L_{n+1}^k(x) = \frac{(2n+k+1-x)L_n^k(x) - (n+k)L_{n-1}^k(x)}{n+1}. \quad (\text{C.4})$$

The first few elements are

$$L_0^k(x) = 1 \quad (\text{C.5})$$

$$L_1^k(x) = 1 + k - x \quad (\text{C.6})$$

$$L_2^k(x) = \frac{1}{2} \left[ x^2 - 2(k+2)x + (k+1)(k+2) \right] \quad (\text{C.7})$$

$$L_3^k(x) = \frac{1}{6} \left[ -x^3 + 3(k+3)x^2 - 3(k+2)(k+3)x + (k+1)(k+2)(k+3) \right] \quad (\text{C.8})$$

# Appendix D

## General Gaussian-binary RBM wave function

### D.1 Derive the wave function

We have seen that the probability of having a set of positions  $\mathbf{x}$  with a set of hidden nodes  $\mathbf{h}$  is given by

$$F(\mathbf{x}, \mathbf{h}) = \frac{1}{Z} \exp(-\beta E(\mathbf{x}, \mathbf{h})) \quad (\text{D.1})$$

where we set  $\beta = 1/kT = 1$ ,  $Z$  is the partition function and  $E(\mathbf{x}, \mathbf{h})$  is the system energy

$$E(\mathbf{x}, \mathbf{h}) = \sum_{i=1}^F \frac{(x_i - a_i)^2}{2\sigma_i^2} - \sum_{j=1}^H b_j h_j - \sum_{i,j=1}^{F,H} \frac{x_i w_{ij} h_j}{\sigma_i^2} \quad (\text{D.2})$$

such that

$$F_{\text{RBM}}(\mathbf{x}, \mathbf{h}) = \exp\left(\sum_{i=1}^F \frac{(x_i - a_i)^2}{2\sigma^2}\right) \exp\left(\sum_{j=1}^H \left(b_j h_j + \sum_{i=1}^F \frac{x_i w_{ij}}{\sigma^2}\right)\right). \quad (\text{D.3})$$

We omit the partition function because it will not affect the results (it is just a normalization constant). The probability of a set of positions only is therefore the sum over all sets of  $\mathbf{h}$ ,  $\{\mathbf{h}\}$ :

$$\begin{aligned} F_{\text{RBM}}(\mathbf{x}) &= \sum_{\{\mathbf{h}\}} \exp\left(\sum_{i=1}^F \frac{(x_i - a_i)^2}{2\sigma^2}\right) \prod_{j=1}^H \exp\left(b_j h_j + \sum_{i=1}^F \frac{x_i w_{ij} h_j}{\sigma^2}\right) \\ &= \sum_{h_1} \sum_{h_2} \dots \sum_{h_N} \exp\left(\sum_{i=1}^F \frac{(x_i - a_i)^2}{2\sigma^2}\right) \exp\left(b_1 h_1 + \sum_{i=1}^F \frac{x_i w_{i1} h_1}{\sigma^2}\right) \times \\ &\quad \exp\left(b_2 h_2 + \sum_{i=1}^F \frac{x_i w_{i2} h_2}{\sigma^2}\right) \dots \exp\left(b_H h_H + \sum_{i=1}^F \frac{x_i w_{iH} h_H}{\sigma^2}\right) \\ &= \exp\left(\sum_{i=1}^F \frac{(x_i - a_i)^2}{2\sigma^2}\right) \prod_{j=1}^H \sum_{h_j=0}^1 \exp\left(b_j h_j + \sum_{i=1}^F \frac{x_i w_{ij} h_j}{\sigma^2}\right) \\ &= \exp\left(\sum_{i=1}^F \frac{(x_i - a_i)^2}{2\sigma^2}\right) \prod_{j=1}^H \left[1 + \exp\left(b_j + \frac{\mathbf{x}^T \mathbf{w}_{*j}}{\sigma^2}\right)\right] \end{aligned} \quad (\text{D.4})$$

## D.2 Find derivatives

A general Gaussian-binary restricted Boltzmann machine has the form

$$\Psi(\mathbf{x}; \mathbf{a}, \mathbf{b}, \mathbf{w}) = \exp\left(-\sum_{i=1}^F \frac{(x_i - a_i)^2}{2\sigma^2}\right) \prod_{j=1}^H \left[1 + \exp(f_j(\mathbf{x}; \mathbf{b}, \mathbf{w}))\right] \quad (\text{D.5})$$

where  $f_j(\mathbf{x}; \mathbf{b}, \mathbf{w})$  is an arbitrary function of  $\mathbf{x}$ ,  $\mathbf{b}$  and  $\mathbf{w}$ . The Gaussian part is straightforward to differentiate, so we will keep our attention on the product, which can be treated as a Jastrow factor,

$$J(\mathbf{x}; \mathbf{b}, \mathbf{w}) = \prod_{j=1}^H \left[1 + \exp(f_j(\mathbf{x}; \mathbf{b}, \mathbf{w}))\right]. \quad (\text{D.6})$$

Henceforth, we will omit the variable  $\mathbf{x}$ ,  $\mathbf{b}$  and  $\mathbf{w}$ . Introducing

$$p_j \equiv \frac{1}{1 + \exp(+f_j)} \quad \wedge \quad n_j \equiv \frac{1}{1 + \exp(-f_j)} \quad (\text{D.7})$$

we find the gradient and Laplacian of  $\ln \Psi$  to be

$$\nabla_k \ln J = \sum_{j=1}^H n_j \nabla_k(f_j) \quad (\text{D.8})$$

and

$$\nabla_k^2 \ln J = \sum_{j=1}^H n_j [\nabla_k^2(f_j) + p_j (\nabla_k(f_j))^2] \quad (\text{D.9})$$

respectively. The parameter update can be found by

$$\frac{\partial}{\partial \alpha_i} \ln J = \sum_{j=1}^H n_j \frac{\partial}{\partial \alpha_i}(f_j). \quad (\text{D.10})$$

and the ratio between wave functions can be found by

$$\frac{J^{\text{new}}}{J^{\text{old}}} = \prod_{j=1}^H \frac{p_j^{\text{old}}}{p_j^{\text{new}}}. \quad (\text{D.11})$$

As a conclusion, what we actually need to calculate to find respective expressions for each wave function is  $\nabla_k(f_j)$ ,  $\nabla_k^2(f_j)$  and  $\partial_{\alpha_i}(f_j)$ . This does also apply for deep restricted Boltzmann machines with Gaussian-binary units.
